Topics

Two period General Equilibrium pricing of intertemporal contracts:

to set up a model we need assumptions regarding:

- ▶ The economic environment: information tree, real part of the economy
- ▶ The market environment: available contracts
- ▶ The variables defining the general equilibrium depend on those two categories.

We will study two models: Arrow-Debreu economy and Finance (or Radner) economy

Environments and general equilibrium

Common assumptions: regarding the **economic environment**

1. the time-information structure;
2. the real part of the economy: intertemporal preferences and availability of resources

Different assumptions regarding the **market environment**

1. simultaneous markets' opening;
2. sequential markets' opening;

Lead to **different definitions of GE** (general equilibrium)
(that may be **equivalent or not**)

The time-information tree

The time-information tree

This refers

- ▶ to the moments in which markets open
- ▶ to the timing of the decisions
- ▶ the information agents have

In discrete time we have to distinguish between

- ▶ time: the timing for **stocks** and prices of stocks
- ▶ periods: the timing for **flows** and prices of flows

Two period: The timing for flow and stock variables

For flow variables

We assume:

- ▶ $t \in \mathbb{T} = \{0, 1\}$ where \mathbb{T} refer to periods
- ▶ information changes along time, from the perspective of period $t = 0$.

Most variables are 2-period random sequences

$$X = \{X_0, X_1\}$$

are determined on the basis of the information known at period $t = 0$:

- ▶ at period $t = 0$, they are observed

$$X_0 = x_0$$

- ▶ for period $t = 1$, they are contingent on the information available at period $t = 0$

$$X_1(\omega), \omega \in (\Omega, \mathcal{F}, \mathbb{P})$$

X_1 is a random variable

Information for a flow variable

The information at period $t = 0$ is:

- ▶ If Ω is discrete and there are N elementary events, the information regarding period $t = 1$ we have

$$X_1 = (x_{1,1}, \dots, x_{1,s}, \dots, x_{1,N})^\top$$

$$P_1 = (\pi_1, \dots, \pi_s, \dots, \pi_N)^\top$$

where $x_{1,s}$ is the **outcome** if event s realizes and π_s its probability

- ▶ and the sequences of possible outcomes and related probabilities are

The time-information tree

Timing of contracts: for stocks

We distinguish:

- ▶ **spot** contracts: contract, delivery and payment done in the same period

contract, payment and delivery

- ▶ **intertemporal or forward** contracts: contract and payment in one period, delivery in a future period

contract and payment delivery

They differ along two dimensions:

- ▶ the **timing** (which may be relevant if there is, v.g., impatience, depreciation)
- ▶ the **information** set associated to the several actions (and prices) involved

Timing of contracts: for flows

► spot contracts

contract, payment and delivery

► forward contracts

contract and payment

delivery

► information

observed

stochastic

The real part of the economy

The real part of the economy

Refers to:

- ▶ **technology**: the type of availability of resources
 - ▶ **exchange** economies: the availability of the resources is independent of decisions throughout time,
 - ▶ **production** economies: availability of resources is dependent on decisions in previous periods
- ▶ **preferences**: choice among random sequences of consumption
- ▶ **distribution** of agents: they homogenous or heterogenous regarding
 - ▶ endowments or technology
 - ▶ preferences
 - ▶ information

Technology

If we consider a flow of resources for agent i :

- ▶ The resource for agent i is a process $\{Y^i\} = \{y_0^i, Y_1^i\}$ where $y_{t,s}^i$ is the endowment of agent i at time t for the state of nature s , with possible realizations and probabilities

$$\begin{array}{c} y_0^i, 1 \\ \hline 0 \qquad \qquad \qquad 1 \qquad \qquad \qquad 2 \end{array} \quad \left(\begin{array}{c} y_{1,1}^i \\ \dots \\ y_{1,s}^i \\ \dots \\ y_{1,N}^i \end{array} \right), \quad \left(\begin{array}{c} \pi_1^i \\ \dots \\ \pi_s^i \\ \dots \\ \pi_N^i \end{array} \right)$$

- ▶ in an **exchange economy**

$$Y_1^i \text{ independent of } y_0^i$$

- ▶ in a **production economy**

$$Y_1^i = F_1^i(y_0^i) \text{ dependent on } y_0^i$$

Preferences

Agent i **chooses** among:

- Sequences of consumption $\{C^i\} = \{c_0^i, C_1^i\}$ is the consumption flow for agent i

$$\begin{array}{c} c_0^i, 1 \\ \hline 0 \qquad \qquad \qquad 1 \qquad \qquad \qquad 2 \end{array} \quad \left(\begin{array}{c} c_{1,1}^i \\ \dots \\ c_{1,s}^i \\ \dots \\ c_{1,N}^i \end{array} \right), \quad \left(\begin{array}{c} \pi_1^i \\ \dots \\ \pi_s^i \\ \dots \\ \pi_N^i \end{array} \right)$$

where the probabilities can be objective or subjective, exogenous or endogenous, homogeneous or heterogeneous

- Evaluated by an **intertemporal utility functional**

$$U^i(\{C^i\}) = U^i(c_0^i, C_1^i)$$

Preferences

We can calculate several marginal utilities

- ▶ marginal utility for a change of consumption at period $t = 0$

$$U_0 = \frac{\partial U(\{C\})}{\partial c_0}$$

- ▶ marginal utility for a change of consumption at period $t = 1$ for state of nature s

$$U_1(s) = \frac{\partial U(\{C\})}{\partial c_{1,s}}, \text{ for } s \in \{1, \dots, N\}$$

- ▶ the intertemporal marginal rates of substitution is a random variable

$$IMRS_{0,1}(s) = \frac{U_0}{U_1(s)}, \text{ for } s \in \{1, \dots, N\}$$

Preferences

The Hicks -Allen elasticities are

- ▶ "own elasticities" for period $t = 0$ and period $t = 1$

$$\varepsilon_0 = -\frac{\frac{\partial U_0}{\partial c_0}}{U_0} c_0, \quad \varepsilon_1(s, s) = -\frac{\frac{\partial U_1(s)}{\partial c_{1,s}}}{U_1(s)} c_{1,s}, \quad \text{for } s \in \{1, \dots, N\}$$

- ▶ crossed intertemporal elasticities

$$\varepsilon_{0,1}(s) = -\frac{\frac{\partial U_0}{\partial c_{1,s}}}{U_0} c_{1,s}, \quad \text{for } s \in \{1, \dots, N\}$$

- ▶ the elasticity of intertemporal substitution is also a random variable

$$IES_{0,1}(s) = \frac{c_0 U_0 + c_{1,s} U_1(s)}{c_{1,s} U_1(s) \varepsilon_0 - 2c_0 U_0 \varepsilon_{0,1}(s) + c_0 U_0 \varepsilon_1(s, s)}, \quad \text{for } s \in \{1, \dots, N\}$$

Preferences

We can also calculate:

- ▶ crossed inter-state elasticities for period $t = 1$

$$\varepsilon_1(s, s') = -\frac{\frac{\partial U_1(s)}{\partial c_{1,s'}}}{U_1(s)} c_{1,s'}, \text{ for } s \neq s' \in \{1, \dots, N\}$$

- ▶ and an associated interstate elasticity of substitution (not commonly done)

Benchmark preferences: von-Neumann Morgenstern

- ▶ The most common utility functional is the **discounted time-additive von-Neumann Morgenstern** functional

$$U(\{C^i\}) = u^i(c_0^i) + \beta^i \mathbb{E}^i[u^i(C_1^i)] = u^i(c_0^i) + \beta^i \sum_{s=1}^N \pi_s^i u^i(c_{1,s}^i)$$

where $0 \leq \pi_s \leq 1$ and $\sum_{s=1}^N \pi_s^i = 1$;

- ▶ or, equivalently

$$U(\{C^i\}) = \mathbb{E}_0^i \left[\sum_{t=0}^{t=1} (\beta^i)^t u^i(c_{t,s}^i) \right]$$

- ▶ Observations
 - ▶ the utility functional $U(\cdot)$ is doubly additive: **linear** as regards **both** time and the states of nature;
 - ▶ probabilities may be objective or subjective
 - ▶ particular relationship between the intertemporal and the risk aversion properties

Benchmark preferences: von-Neumann Morgenstern

- ▶ Write it as $U(c_0, C_1) = u(c_0) + \beta \sum_{s=1}^N \pi_s u(c_{1,s})$
- ▶ Then the marginal utilities are

$$U_0 = u'(c_0) \text{ and } U_1(s) = \beta \pi_s u'(c_{1,s}), \text{ for } s \in \{1, \dots, N\}$$

- ▶ The intertemporal marginal rate of substitution is state-dependent (random variable)

$$IMRS_{0,1}(s) = \frac{u'(c_0)}{\beta \pi_s u'(c_{1,s})}, \text{ for } s \in \{1, \dots, N\}$$

Benchmark preferences: von-Neumann Morgenstern

The Hicks-Allen elasticities are

- For period $t = 0$ and period $t = 1$

$$\varepsilon_0 = -\frac{u''(c_0)}{u'(c_0)} c_0, \quad \varepsilon_1(s) = -\frac{u''(c_{1,s})}{u'(c_{1,s})} c_{1,s}, \quad s = 1, \dots, N$$

- but the intertemporal elasticities are equal to zero

$$\varepsilon_{0,1}(s) = 0, \quad \text{for all } s \in \{1, \dots, N\}$$

(because of the separability between c_0 and C_1)

- Therefore, the elasticity of intertemporal substitution

$$IES_{0,1}(s) = \frac{c_0 u'(c_0) + \beta \pi_s u'(c_{1,s})}{\beta \pi_s u'(c_{1,s}) c_{1,s} \varepsilon_0 + c_0 u'(c_0) \varepsilon_1(s)}$$

is also a random variable but has not intertemporal substitution effects

Benchmark preferences: von-Neumann Morgenstern

- ▶ The Hicks-Allen elasticities between states of nature are also equal to zero

$$\varepsilon_1(s, s') = 0, \text{ for all } s \neq s' \in \{1, \dots, N\}$$

- ▶ this means that the preferences regarding different states of nature are **independent**

Benchmark preferences: von-Neumann Morgenstern

- If we assume a constant relative risk aversion utility function

$$u(c) = \frac{c^{1-\zeta} - 1}{1-\zeta} \Rightarrow u'(c) = c^{-\zeta}, \quad u''(c) = -\zeta c^{-\zeta-1}$$

- where the coefficient of relative risk aversion ϱ_r is

$$\varrho_r = -\frac{u''(c)}{u'(c)} c = \zeta > 0$$

- then

$$\begin{aligned}\varepsilon_0 &= \zeta \\ \varepsilon_1(s, s') &= \zeta\end{aligned}$$

is state-independent.

Benchmark preferences: von-Neumann Morgenstern

- ▶ The elasticity of intertemporal substitution

$$IES_{0,1}(s) = \frac{1}{\zeta}$$

is:

(1) **state independent**

(2) is equal to the inverse of the CRRA

- ▶ This means that the we **cannot distinguish the intertemporal and the stochastic properties of preferences**
- ▶ Which is counterfactual (see Thimme (2017))

Epstein-Zin preferences

- ▶ Are becoming popular among macroeconomists
- ▶ They distinguish between the intertemporal preferences and risk aversion by parameterizing them with different parameters
- ▶ Most models are multi-period

Epstein-Zin preferences

- ▶ A two period version of EZ preferences
- ▶ Let $U(c_0, C_1)$ be the intertemporal utility functional
- ▶ There is an aggregator $V(c_0, C_1) = u^{-1}(U(c_0, C_1))$

$$V(c_0, C_1) = (1 - \beta)u(c_0) + \beta u(c_1^c)$$

where c_1^c is the **certainty equivalent of consumption at period $t = 1$:**

- ▶ intertemporal preferences are represented by $u(c)$, which is increasing and concave $u''(c) < 0 < u'(c)$
- ▶ choice among states of nature is represented by

$$v(c_1^c) = \mathbb{E}[v(C_1)]$$

is a utility function displaying risk aversion

Epstein-Zin preferences

- Therefore

$$V(c_0, C_1) = (1 - \beta)u(c_0) + \beta u\left(v^{-1}\left(\mathbb{E}[v(C_1)]\right)\right)$$

- For instance:

$$u(c) = \frac{c^{1-\zeta} - 1}{1 - \zeta}$$
$$v(c) = \ln(c) \Leftrightarrow c = e^v$$

- then for this case $\varrho = 1$,

$$V(\{C\}) = (1 - \beta) \frac{c_0^{1-\zeta} - 1}{1 - \zeta} + \beta \frac{e^{(1-\zeta)\mathbb{E}[\ln(C_1)]} - 1}{1 - \zeta}$$

- It can be proved that, if $\zeta = \varrho$ this model reduces to the benchmark case (prove this)

Distribution of agents

Distribution

- ▶ The **idiosyncratic** components defining a consumer are:
 - ▶ endowments (Y^i)
 - ▶ preferences (β^i, u^i) (impatience, risk aversion)
 - ▶ information \mathbb{P}^i (only make sense with subjective probabilities)
- ▶ Agents can be **homogeneous** or **heterogeneous** regarding one or all of the previous variables and parameters
 - in a **homogeneous**, or **representative agent** economy:
endowments, preferences and information are equal, i.e,
 $Y^1 = Y^I = Y$, etc
 - in a **heterogeneous** economy: **agents differ** in at least one of the three dimensions: endowments ($Y^i \neq Y^j$), preferences ($\beta^i \neq \beta^j$ or $u^i(\cdot) \neq u^j(\cdot)$), or information ($\mathbb{P}^i \neq \mathbb{P}^j$)

The market structure

Autarky versus trade economies

The economies are distinguished by the exchanges that agents can make.

► In **autarky** we will have

$$c_{t,s}^i = y_{t,s}^i, \quad t = 0, 1, \quad s = 1, \dots, N$$

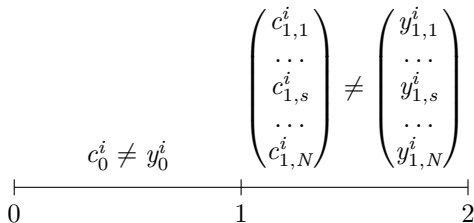

$$c_0^i = y_0^i \qquad \begin{pmatrix} c_{1,1}^i \\ \dots \\ c_{1,s}^i \\ \dots \\ c_{1,N}^i \end{pmatrix} = \begin{pmatrix} y_{1,1}^i \\ \dots \\ y_{1,s}^i \\ \dots \\ y_{1,N}^i \end{pmatrix}$$

Autarky versus trade economies

- If there are **markets for intertemporal transfers of contingent goods**, agents can trade and be able to make

$$c_{t,s}^i \neq y_{t,s}^i, \quad t = 0, 1, \quad s = 1, \dots, N$$

by shifting resources across **time** and **states of nature**.

$$\begin{array}{c} c_0^i \neq y_0^i \\ \hline \begin{pmatrix} c_{1,1}^i \\ \dots \\ c_{1,s}^i \\ \dots \\ c_{1,N}^i \end{pmatrix} \neq \begin{pmatrix} y_{1,1}^i \\ \dots \\ y_{1,s}^i \\ \dots \\ y_{1,N}^i \end{pmatrix} \end{array}$$

Real versus financial markets

We distinguish further:

- ▶ **real markets:**
market for goods,
which can be spot or forward
prices and deliveries are referred to **periods**
- ▶ **financial markets:**
market on financial instruments,
which are always forward (in an economic sense)
and prices and deliveries are referred to **times**

Markets and general equilibrium models

Simultaneous versus sequential market economies

We consider next two economies which are distinguished by the type of intertemporal contracts available:

- ▶ **Arrow Debreu economies:**

there are AD contingent goods traded in spot and forward **real** markets \Rightarrow there is **simultaneous market equilibrium**

- ▶ **finance economies:**

Radner economies in which **financial** assets are traded \Rightarrow there is **sequential market equilibrium**

They can be **equivalent under some conditions**, i.e., have the same equilibrium allocations

Julian Thimme. Intertemporal Substitution In Consumption: A Literature Review. *Journal of Economic Surveys*, 31(1):226–257, February 2017. URL <https://ideas.repec.org/a/bla/jecsur/v31y2017i1p226-257.html>.
