Functional calculus and optimal control of ODEs

Chapter 7

Introduction to functional calculus

7.1 Introduction

In several areas in economics functionals over functions $y : X \subseteq \mathbb{R} \rightarrow \mathbb{R}$ of the following types

$$F[y] = \int_X f(x, y(x)) dx \quad (7.1)$$

and

$$F[y] = g\left(\int_X f(x, y(x)) dx\right) \quad (7.2)$$

where g are both functions with appropriate properties. Those functionals are infinite-dimensional analogs to functionals over $y : \mathbb{N} \rightarrow \mathbb{R}$

$$F(y) = \sum_{i=1}^n f(y_i, i) \text{ or } F(y) = g\left(\sum_{i=1}^n f(y_i, i)\right).$$

As economic problems involve optimizing functionals (??) constrained or not by side conditions which could also be functionals of the same types, we need to use results from generalized calculus, or, more generally calculus an optimization over normed vector spaces.

In addition, we will see in the next chapter that the simplest calculus of variation problem is

$$\max_{y(\cdot)} F[y] = \int_X f(x, y(x), y'(x)) dx,$$

whose solution involves generalized calculus, in analogy with the classical optimization problem in which the necessary conditions consist in setting a derivative to zero.

Next we present the main results from generalized calculus and use them to solve some infinite-dimensional optimization problems.

7.2 Some results in generalized calculus

7.2.1 Functionals and Gâteaux differential

Consider two normed vector spaces: can be spaces of numbers, continuous functions, continuous differentiable functions, bounded functions or distributions together with a norm

An operator as a mapping between two normed vector spaces.

A **functional** is a mapping between a normed vector space and the space of real numbers.

Let y belong to the space of functions \mathcal{Y} which map $X \subseteq \mathbb{R} \mapsto \mathbb{R}$.

Consider in particular a functional over the space of functions $y : X \subseteq \mathbb{R} \rightarrow \mathbb{R}$. The function is continuous at point x_0 if $\lim_{x \rightarrow x_0} y(x) = y(x_0)$ for x in any neighborhood of x_0 . In particular, this means that $y(x_0^+) = y(x_0^-) = y(x_0)$ where $y(x_0^-) = \lim_{x \uparrow x_0}$ and $y(x_0^+) = \lim_{x \downarrow x_0}$, that the limits to the right and to the left are equal. The function is continuous if it is continuous to all points $x \in X$.

The variation of the functional is denoted as

$$\Delta F[y] = F[y + dy] - F[y]$$

In particular, the variation of the functional in the direction $h(x) \in \mathcal{Y}$ is

$$D F[y] = F[y + \epsilon h] - F[y].$$

The Gâteaux differential is defined as the variation of the functional in the direction $h \in \mathcal{Y}$ when the constant ϵ is infinitesimal

$$D_{\eta(\cdot)} F[y] = \lim_{\epsilon \rightarrow 0} \frac{F[y + \epsilon \eta] - F[y]}{\epsilon}. \quad (7.3)$$

Equivalently we have ¹

$$F[y + \epsilon \eta] = F[y] + D_{\eta(\cdot)} F[y] \epsilon + o(\epsilon)$$

In analogy with the case of finite-dimensional analysis² it can be shown that the Gâteaux differential is a linear functional of $\eta(x)$. If y is a linear operator in a normed vector space, it is bounded and we can invoke the Riesz-Frechet theorem (Riesz and Sz.-Nagy, 1955, p. 61) which states that if $G[\eta]$ is a bounded operator in a inner-product space, then there is a ζ such that $G[\eta]$ can be

¹To see this observe that equation (7.3) is equivalent to

$$\lim_{\epsilon \rightarrow 0} \frac{F[y + \epsilon \eta] - F[y]}{\epsilon} - D_{\eta(\cdot)} F[y] = 0$$

and therefore, to

$$\lim_{\epsilon \rightarrow 0} \frac{F[y + \epsilon \eta] - F[y] - D_{\eta(\cdot)} F[y] \epsilon}{\epsilon} = 0.$$

Writing the numerator as $g(\epsilon)$ which is possible because a functional has its range in set \mathbb{R} , we can use the "little-o" notation, such that $o(\epsilon) = \lim_{\epsilon \rightarrow 0} \frac{g(\epsilon)}{\epsilon} = 0$.

²This generalizes the concept of directional derivative in elementary calculus. Let $f(\mathbf{y}) = f(y_1, \dots, y_n)$ the directional derivative in the direction given by the vector $\mathbf{h} = (h_1, \dots, h_n)^\top$ is

$$D_{\mathbf{h}} f(\mathbf{y}) \equiv \lim_{\epsilon \rightarrow 0} \frac{f(\mathbf{y} + \epsilon \mathbf{h}) - f(\mathbf{y})}{\epsilon} = \sum_i \frac{\partial f(\mathbf{y})}{\partial y_i} h_i$$

is a linear functional of $\mathbf{h} = (h_1, \dots, h_n)^\top$.

represented by $G[\eta] = \langle \zeta, \eta \rangle$ and $\|G\| = \|\zeta\|$. This means that the Gâteaux differential of a linear functional admits the representation

$$D_{\eta(\cdot)} F[y] = \int_X d(x) \eta(x) dx$$

If we consider \mathcal{Y} as a space of distributions ³ we call **Gâteaux derivative** at point x , to the Gâteaux differential in which the perturbation is a Dirac- δ generalized function at a singular at the point x ,

$$d(x) = \frac{\delta F[y]}{\delta y(x)} = \int_X d(s) \delta(s - x) ds.$$

Therefore, we can represent the Gâteaux differential a linear functional as regards any perturbation $\eta(\cdot)$ by

$$D_{\eta(\cdot)} F[y] = \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx. \quad (7.4)$$

We can extend the definition to second order variations

$$\Delta^2 F[y] = \Delta (\Delta F[y + d_1 y] - \Delta F[y]) = F[y + d_1 y + d_2 y] - F[y + d_2 y] - F[y + d_1 y] + F[y].$$

The second-order Gâteaux differential of functional $F[y]$ is defined as

$$D_{\eta_1(\cdot), \eta_2(\cdot)} F[y] = \lim_{\varepsilon_2 \rightarrow 0} \lim_{\varepsilon_1 \rightarrow 0} \frac{F[y + \varepsilon_1 \eta_1 + \varepsilon_2 \eta_2] - F[y + \varepsilon_2 \eta_2] - F[y + \varepsilon_1 \eta_1] + F[y]}{\varepsilon_1 \varepsilon_2}.$$

Using our previous results we can write

$$D_{\eta_1(\cdot), \eta_2(\cdot)} F[y] = \int_X \int_X \frac{\delta^2 F[y]}{\delta y(x) \delta y(x')} \eta_1(x) \eta_2(x') dx dx'.$$

and the second-order Gâteaux derivative, associated to perturbarions $\eta(x)$ and $\zeta(x)$ ⁴is

$$\frac{\delta^2 F[y]}{\delta y(x) \delta y(x')}.$$

We conjecture that there is symmetry

$$D_{\eta_1(\cdot), \eta_2(\cdot)} F[y] = D_{\eta_2(\cdot), \eta_1(\cdot)} F[y]$$

Therefore a generalization of the second order Taylor expansion is

$$F[y + \varepsilon \eta] = F[y] + D_{\eta(\cdot)} F[y] \varepsilon + \frac{1}{2} D_{\eta(\cdot)}^2 F[y] \varepsilon^2 + o(\varepsilon^2), \quad (7.5)$$

where $D_{\eta(\cdot)}^2 F[y] \equiv D_{\eta(\cdot), \eta(\cdot)} F[y]$.

There are general properties of functionals over one-dimensional functions of one variable, that is $y \in \mathcal{Y}$, $y : X \subseteq \mathbb{R} \rightarrow \mathbb{R}$, where $F : \mathcal{Y} \rightarrow \mathbb{R}$.

³This is the analog to a partial derivative in classical calculus. This is a type of possibly ad-hoc concept which is used in mathematical physics and which is useful for our purposes. In particular it allows to determine elasticities of substitution in a continuum setting. References...

⁴We do not use the notation because $\eta(x)$ is a function of x , and reserve it to the derivative of $\eta(x)$.

1. multiplication by a constant: let $a \in \mathbb{R}$ be a number, then $D_{\eta(\cdot)}\{a F[y]\} = a D_{\eta(\cdot)}F[y]$
2. sum of functionals: let $F_1[y]$ and $F_2[y]$ be two functionals, then $D_{\eta(\cdot)}\{F_1[y] + F_2[y]\} = D_{\eta(\cdot)}F_1[y] + D_{\eta(\cdot)}F_2[y]$
3. product rule: let $F_1[y]$ and $F_2[y]$ be two functionals, then $D_{\eta(\cdot)}\{F_1[y] \cdot F_2[y]\} = \{D_{\eta(\cdot)}F_1[y]\} \cdot F_2[y] + \{D_{\eta(\cdot)}F_2[y]\} \cdot F_1[y]$
4. chain rule: let $f : \mathbb{R} \rightarrow \mathbb{R}$ be a monotonic function and $F_1[y]$ be a functional, then $D_{\eta(\cdot)}\{f(F_1[y])\} = f'(F_1[y]) \{D_{\eta(\cdot)}F_1[y]\}$

7.2.2 Linear functionals

From now on we will consider the following two types of functionals which are common in economics:

$$F[y] = \int_X f(y(x)) dx, \quad (7.6)$$

where we assume that function $f(\cdot)$ is a smooth function, i.e. $f \in C^2(\mathbb{R})$, and the integral exists, and

$$G[y] = g(F[y]) \equiv g\left(\int_X f(y(x)) dx\right) \quad (7.7)$$

where $g(\cdot)$ is also a $C^2(\mathbb{R})$ function.

From now on we call generalized differential to the differential (in the Gâteaux sense) of functional (7.7) to

$$D_{\eta(\cdot)}F[y] = \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx \quad (7.8)$$

where

$$\frac{\delta F[y]}{\delta y(x)} = \frac{\partial f(y(x))}{\partial y}, \text{ for each } x \in X,$$

is the generalized derivative of functional (7.6).

The generalized differential of functional (7.7) is

$$D_{\eta(\cdot)}G[y] = \int_X \frac{\delta G[y]}{\delta y(x)} \eta(x) dx \quad (7.9)$$

where

$$\frac{\delta G[y]}{\delta y(x)} = g'(F[y]) \frac{\partial f(y(x))}{\partial y}, \text{ for each } x \in X.$$

The second-order generalized differential of (7.6) is

$$D_{\eta(\cdot)}^2 F[y] = \int_X \frac{\delta^2 F[y]}{\delta y(x)^2} \eta(x)^2 dx \quad (7.10)$$

where the second-order generalized derivative is

$$\frac{\delta^2 F[y]}{\delta y(x)^2} = \frac{\partial^2 f(y)}{\partial y^2}, \text{ for each } x \in X.$$

The second-order generalized differential of (7.7) is

$$D_{\eta(\cdot)}^2 \mathbf{G}[y] = \int_X \frac{\delta^2 \mathbf{G}[y]}{\delta y(x)^2} \eta(x)^2 dx \quad (7.11)$$

where the second-order generalized derivative is

$$\frac{\delta^2 \mathbf{G}[y]}{\delta y(x)^2} = g''(\mathbf{F}[y]) \left(\frac{\partial f(y(x))}{\partial y} \right)^2 + g'(\mathbf{F}[y]) \frac{\partial^2 f(y(x))}{\partial y^2}, \text{ for each } x \in X, \text{ for each } x \in X.$$

Examples: Next we present the generalized derivatives for several functionals:

1. for $\mathbf{F}[y] = \int_X a dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = \frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = 0$;
2. for $\mathbf{F}[y] = \int_X a y(x) dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = a$ and $\frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = 0$;
3. for $\mathbf{F}[y] = \int_X y(x)^2 dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = 2y(x)$ and $\frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = 2$;
4. for $\mathbf{F}[y] = \int_X e^{y(x)} dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = \frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = e^{y(x)}$;
5. for $\mathbf{F}[y] = \int_X y(x)^\theta dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = \theta y(x)^{\theta-1}$ and $\frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = \theta(\theta-1) y(x)^{\theta-2}$;
6. and for $\mathbf{F}[y] = \int_X e^{g(y(x))} dx$, we have $\frac{\delta \mathbf{F}[y]}{\delta y(x)} = g'(y(x)) e^{g(y(x))}$ and $\frac{\delta^2 \mathbf{F}[y]}{\delta y(x)^2} = g''(y(x)) e^{g(y(x))} + (g'(y(x)))^2 e^{g(y(x))}$.

"Spike" perturbations

In particular, for a "spike" perturbation at point $x = x_0$, represented by a delta ⁵ we have a functional generalization to the partial derivative⁶

$$D_{\delta(x_0)} \mathbf{F}[y] = \int_X \frac{\delta \mathbf{F}[y]}{\delta y(x)} \delta(x - x_0) dx = \frac{\delta \mathbf{F}[y]}{\delta y(x_0)} = f'(y(x_0)). \quad (7.12)$$

7.2.3 Functionals over two-dimensional spaces

We can In this section definitions to functionals over two-dimensional functions of one variable, that is $\mathbf{y} \in \mathcal{Y}$, $\mathbf{y} : X \subseteq \mathbb{R} \rightarrow \mathbb{R}^2$, where $\mathbf{F} : \mathcal{Y} \rightarrow \mathbb{R}$, where $\mathbf{y}(x) = (y_1(x), y_2(x))^\top$.

⁵Dirac- δ is not a function but a distribution. It has the following properties

$$\delta(x - x_0) = \begin{cases} 0 & \text{if } x \neq x_0 \\ \infty & \text{if } x = x_0 \end{cases},$$

$$\int_{-\infty}^{\infty} \delta(x) dx = 1 \text{ and } \delta_{-\infty}^{\infty} \delta(x - y_0) y(x) dx = y(x_0).$$

⁶In mathematical physics this is sometimes called as a Volterra derivative.

In particular, let

$$F[\mathbf{y}] = \int_X f(x, y_1(x), y_2(x)) dx. \quad (7.13)$$

In this case, for a perturbation $\boldsymbol{\eta}(x) = (\eta_1(x), \eta_2(x))^\top$, we definition

$$D_{\boldsymbol{\eta}(\cdot)} F[\mathbf{y}] = \lim_{\varepsilon \rightarrow 0} \frac{F[\mathbf{y} + \varepsilon \boldsymbol{\eta}] - F[\mathbf{y}]}{\varepsilon},$$

which implies that the functional (7.13) has the differential

$$\begin{aligned} D_{\boldsymbol{\eta}(\cdot)} F[\mathbf{y}] &= \int_X \left\langle \frac{\delta F[\mathbf{y}]}{\delta \mathbf{y}(x)}, \boldsymbol{\eta} \right\rangle(x) dx \\ &= \int_X \left(\frac{\delta F[\mathbf{y}]}{\delta y_1(x)} \eta_1(x) + \frac{\delta F[\mathbf{y}]}{\delta y_2(x)} \eta_2(x) \right) dx, \end{aligned} \quad (7.14)$$

where the generaliized gradient is

$$\frac{\delta F[\mathbf{y}]}{\delta \mathbf{y}(x)} = \begin{pmatrix} \frac{\delta F[\mathbf{y}]}{\delta y_1(x)} \\ \frac{\delta F[\mathbf{y}]}{\delta y_2(x)} \end{pmatrix}.$$

Example:

The functional $F[\mathbf{y}] = \int_X y_1(x)^\alpha y_2(x)^{1-\alpha} dx$, for a number α , then the generalized gradient is

$$\frac{\delta F[\mathbf{y}]}{\delta \mathbf{y}(x)} = \begin{pmatrix} \alpha y_1(x)^{\alpha-1} y_2(x)^{1-\alpha} \\ (1-\alpha) y_1(x)^\alpha y_2(x)^{-\alpha} \end{pmatrix}.$$

7.2.4 Functionals involving first-order derivatives

The previous result is useful to address the derivation of the next functional which is used in calculus of variations

$$F[y] = \int_X f(x, y(x), y'(x)) dx, \quad (7.15)$$

where we assume function $f(\cdot)$ is continuous and continuous differentiable in (y, y') . The (first-order) generalized differential is

$$D_{\eta(\cdot)} F[y] = \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx + \int_X \frac{\partial f}{\partial y'}(x) \eta(x) \quad (7.16)$$

where the generalized derivative is

$$\frac{\delta F[y]}{\delta y(x)} = \frac{\partial f(x, y(x), y'(x))}{\partial y} - \frac{d}{dx} \left(\frac{\partial f(x, y(x), y'(x))}{\partial y'} \right) \quad (7.17)$$

and

$$\int_X \frac{\partial f(x)}{\partial y'} \eta(x) = \frac{\partial f(x_1, y(x_1), y'(x_1))}{\partial y'} \eta(x_1) - \frac{\partial f(x_0, y(x_0), y'(x_0))}{\partial y'} \eta(x_0)$$

if $X = [x_0, x_1]$ is a closed set, or

$$\int_X f(x) \eta(x) = \lim_{x \uparrow x_1} \frac{\partial f(x)}{\partial y'} \eta(x) - \lim_{x \downarrow x_0} \frac{\partial f(x)}{\partial y'} \eta(x)$$

if $X = (x_0, x_1)$ is an open set.

To prove this, observe that our perturbations are $y(x) \rightarrow y(x) + \varepsilon \eta(x)$ and $y'(x) \rightarrow y'(x) + \varepsilon \eta'(x)$, which using equation (7.14) yields

$$\begin{aligned} D_{\eta(\cdot)} F[y] &= \int_X \left(\frac{\delta F[y]}{\delta y(x)} \eta(x) + \frac{\delta F[y]}{\delta y'(x)} \eta'(x) \right) dx \\ &= \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx + \int_X \frac{\delta F[y]}{\delta y'(x)} \eta'(x) dx \\ &= \int_X \frac{\partial f(x, y(x), y'(x))}{\partial y} \eta(x) dx + \int_X \frac{\partial f(x, y(x), y'(x))}{\partial y'} \eta'(x) dx \end{aligned}$$

Integrating by parts the second integral, we obtain

$$\int_X \frac{\partial f(x, y(x), y'(x))}{\partial y'} \eta'(x) dx = \int_X \frac{\partial f(x, y(x), y'(x))}{\partial y'} \eta(x) - \int_X \frac{d}{dx} \left(\frac{\partial f(x, y(x), y'(x))}{\partial y'} \right) \eta(x) dx,$$

that, upon substitution, yields the differential (7.16).

7.2.5 Functionals involving second-order derivatives

Now consider the integral where function f depends on the first and second derivatives of y ,

$$F[y] = \int_X f(x, y(x), y'(x), y''(x)) dx. \quad (7.18)$$

where we assume function $f(\cdot)$ is continuous and continuous differentiable at least up to the second order in (y, y', y'') .

The Gâteaux differential of functional (7.18) is

$$D_{\eta(\cdot)} F[y] = \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx + \int_X \frac{\partial f(x)}{\partial y'} \eta(x) + \int_X \frac{\partial f(x)}{\partial y''} \eta'(x) - \int_X \frac{d}{dx} \left(\frac{\partial f(x)}{\partial y'} \right) \eta(x) \quad (7.19)$$

where we denote $f(x) = f(x, y(x), y'(x), y''(x))$, the Gâteaux derivative is

$$\frac{\delta F[y]}{\delta y(x)} = \frac{\partial f(x)}{\partial y} - \frac{d}{dx} \left(\frac{\partial f(x)}{\partial y'} \right) + \frac{d^2}{dx^2} \left(\frac{\partial f(x)}{\partial y''} \right), \quad (7.20)$$

and, in the case in which set X is closed

$$\begin{aligned} \int_X \frac{\partial f(x)}{\partial y'} \eta(x) &= \frac{\partial f(x_1)}{\partial y'} \eta(x_1) - \frac{\partial f(x_0)}{\partial y'} \eta(x_0) \\ \int_X \frac{\partial f(x)}{\partial y''} \eta'(x) &= \frac{\partial f(x_1)}{\partial y''} \eta'(x_1) - \frac{\partial f(x_0)}{\partial y''} \eta'(x_0) \\ \int_X \frac{d}{dx} \left(\frac{\partial f(x)}{\partial y''} \right) \eta(x) &= \frac{d}{dx} \left(\frac{\partial f(x_1)}{\partial y''} \right) \eta(x_1) - \frac{d}{dx} \left(\frac{\partial f(x_0)}{\partial y''} \right) \eta(x_0). \end{aligned}$$

To prove this, we have

$$\begin{aligned}
D_{\eta(\cdot)} F[y] &= \int_X \left(\frac{\delta F[y]}{\delta y(x)} \eta(x) + \frac{\delta F[y]}{\delta y'(x)} \eta'(x) + \frac{\delta F[y]}{\delta y''(x)} \eta''(x) \right) dx \\
&= \int_X \frac{\delta F[y]}{\delta y(x)} \eta(x) dx + \int_X \frac{\delta F[y]}{\delta y'(x)} \eta'(x) dx + \int_X \frac{\delta F[y]}{\delta y''(x)} \eta''(x) dx \\
&= \int_X \frac{\partial f(x)}{\partial y} \eta(x) dx + \int_X \frac{\partial f(x)}{\partial y'} \eta'(x) dx + \int_X \frac{\partial f(x)}{\partial y''} \eta''(x) dx.
\end{aligned}$$

Integrating by parts the second integral, we have

$$\int_X \frac{\partial f(x)}{\partial y'} \eta'(x) dx = \int_X \frac{\partial f(x)}{\partial y'} \eta(x) - \int_X \frac{d}{dx} \left(\frac{\partial f(x)}{\partial y'} \right) \eta(x) dx.$$

Integrating by parts the third integral,⁷ we have

$$\begin{aligned}
\int_X \frac{\partial f(x)}{\partial y''} \eta''(x) dx &= \int_X \frac{\partial f(x)}{\partial y''} \eta'(x) - \int_X \frac{d}{dx} \frac{\partial f(x)}{\partial y''} \eta'(x) dx \\
&\quad + \int_X \frac{d^2}{dx^2} \frac{\partial f(x)}{\partial y''} \eta(x) dx.
\end{aligned}$$

7.2.6 Functionals over higher-dimensional independent variables

We can extend those definitions for functionals $F[y]$ over functions over higher dimensional $y \in \mathcal{Y}$ which is the space of functions $\mathbf{x} \subseteq \mathbb{R}^n \mapsto \mathbb{R}$. The simplest case involves functionals over functions $y(\mathbf{x}) = y(x_1, x_2)$.

The simplest functional is

$$F[y] = \int_X f(\mathbf{x}, y(\mathbf{x})) d\mathbf{x} = \int_{X_1} \int_{X_2} f(x_1, x_2, y(x_1, x_2)) dx_2 dx_1 \quad (7.21)$$

where $f(\cdot, y)$ is continuously differentiable in y and $X = X_1 \times X_2 \subseteq \mathbb{R}^2$. Introducing the perturbation $y(\mathbf{x}) \rightarrow y(\mathbf{x}) + \varepsilon \eta(\mathbf{x})$ is

The Gâteaux differential is

$$D_{\eta(\cdot)} F[y] = \int_X \frac{\delta F[y]}{\delta y(\mathbf{x})} \eta(\mathbf{x}) d\mathbf{x} = \int_{X_1} \int_{X_2} \frac{\delta F[y]}{\delta y(x_1, x_2)} \eta(x_1, x_2) dx_2 dx_1 \quad (7.22)$$

where the Gâteaux derivative is

$$\frac{\delta F[y]}{\delta y(\mathbf{x})} = \frac{\partial f(\mathbf{x}, y(\mathbf{x}))}{\partial y} \quad (7.23)$$

For the functional with first derivatives,

$$\begin{aligned}
F[y] &= \int_X f(\mathbf{x}, y(\mathbf{x}), \nabla y(\mathbf{x})) d\mathbf{x} = \\
&\quad \int_{X_1} \int_{X_2} f(x_1, x_2, y(x_1, x_2), y_{x_1}(x_1, x_2), y_{x_2}(x_1, x_2)) dx_2 dx_1
\end{aligned} \quad (7.24)$$

⁷This is because

$$\int uv'' dx = uv' - \int u'v' dx = uv' - \left(u'v - \int u''v dx \right).$$

where $f(\cdot, y)$ is continuously differentiable in $(y, \nabla y)$, $X = X_1 \times X_2 \subseteq \mathbb{R}^2$ and $y_{x_i}(\mathbf{x})$ denote the partial derivatives for $i = 1, 2$. Introducing, the perturbations $y(\mathbf{x}) \rightarrow y(\mathbf{x}) + \varepsilon \eta(\mathbf{x})$ and $\nabla y(\mathbf{x}) \rightarrow \nabla y(\mathbf{x}) + \varepsilon \nabla \eta(\mathbf{x})$

The Gâteaux differential is

$$D_{\eta(\cdot)} F[y] = \int_X \frac{\delta F[y]}{\delta y(\mathbf{x})} \eta(\mathbf{x}) d\mathbf{x} = \int_{X_1} \int_{X_2} \frac{\delta F[y]}{\delta y(x_1, x_2)} \eta(x_1, x_2) dx_2 dx_1 \quad (7.25)$$

where the Gâteaux derivative is

$$\frac{\delta F[y]}{\delta y(x_1, x_2)} = \frac{\partial f(\mathbf{x}, y(\mathbf{x}))}{\partial y} \quad (7.26)$$

7.3 Applications

Next we present some infinite-dimensional functionals which are relatively common in economic models.

7.3.1 Generalized means

The **generalized mean** is very common functional which is used in economics. It is a functional on $x : I \rightarrow \mathbb{R}$, where $I \subset \mathbb{R}_+$,

$$M_\rho[x] = \left(\int_I w(i) x(i)^\rho di \right)^{\frac{1}{\rho}}, \text{ for } \rho \in [-\infty, \infty] \quad (7.27)$$

where $w : I \rightarrow (0, 1)$ is a weighting function such that

$$\int_I w(i) di = 1.$$

This functional can be seen as an infinite-dimensional generalization of the CES aggregator.

Proposition 1. *The geometrical mean has the special cases:*

1. if $\rho = 0$ then $M_0[x] = \exp \left(\int_I \ln(x(i)^{w(i)}) di \right)$ (geometric mean, in particular a generalized Cobb-Douglas function)
2. if $\rho = 1$ then $M_1[x] = \int_I w(i) x(i) di$ (arithmetic mean)
3. if $\rho = -1$ then $M_{-1}[x] = \frac{1}{\int_I \frac{w(i)}{x(i)} di}$ (harmonic mean)
4. if $\rho = -\infty$ then $M_{-\infty}[x] = \min\{x\}$ (in particular a generalized Leontieff production function)
5. if $\rho = \infty$ then $M_\infty[x] = \max\{x\}$

In general $\min_x[x] \leq M_\rho[x] \leq \max_x[x]$

Proof. We can write equation (7.27) equivalently as

$$M_\rho[x] = \exp \left\{ \ln \left[\left(\int_I w(i) x(i)^\rho di \right)^{\frac{1}{\rho}} \right] \right\} = \exp \left\{ \frac{1}{\rho} \ln \left(\int_I w(i) x(i)^\rho di \right) \right\}.$$

But

$$\begin{aligned} \lim_{\rho \rightarrow 0} \frac{\ln \left(\int_I w(i) x(i)^\rho di \right)}{\rho} &= \lim_{\rho \rightarrow 0} \frac{\int_I w(i) \ln(x(i)) x(i)^\rho di}{1} \\ &= \int_I w(i) \ln(x(i)) di = \int_I \ln(x(i)^{w(i)}) di \end{aligned}$$

Then $M_0[x] = \exp \left(\int_I \ln(x(i)^{w(i)}) di \right)$. The generalized mean for $\rho = 1$ and $\rho = -1$ are obtained by direct substitution.

If function $x : \mathbb{R} \rightarrow X$ and $x \in L_\infty(X)$ then there is a maximum $x^* = \|x\|_\infty$ and we can write

$$M_\infty[x] = \lim_{\rho \rightarrow \infty} x^* \left(\int_I w(i) \left(\frac{x(i)}{x^*} \right)^\rho di \right)^{\frac{1}{\rho}} = \lim_{\psi \rightarrow 0} x^* \left(\int_I w(i) \left(\frac{x(i)}{x^*} \right)^{\frac{1}{\psi}} di \right)^\psi = x^*$$

where $\psi = 1/\rho$. For any ρ we have $M_\rho[x] = M_{-\rho} \left[\frac{1}{x} \right]$. If $x \in L_\infty(X)$ as $\max \left[\frac{1}{x} \right] = \min[x]$ then

$$M_{-\infty}[x] = \lim_{\rho \rightarrow \infty} \frac{1}{M_\rho \left[\frac{1}{x} \right]} = \min[x]$$

□

The generalized derivative of equation (7.27), for a finite ρ , is

$$\frac{\delta M_\rho[x]}{\delta x(i)} = w(i) \left(\frac{M_\rho[x]}{x(i)} \right)^{1-\rho}, \text{ for each } i \in I.$$

7.3.2 Varieties in consumption theory

Let $c(i)$ be the quantity of good of variety $i \in I \subseteq [0, \infty)$. We denote by $c(\iota)$ the quantity of a specific variety $i = \iota \in I$. We can see $c(\iota) = \int_I \delta(i - j\iota) c(i) di$. We denote C a variety distribution $C = (c(i))_{i \in I}$. The set of variety distributions C is the function space \mathcal{C} .

A utility functional $U[c]$ maps a variety distribution into value, which is a number, i.e. $U : \mathcal{C} \rightarrow \mathbb{R}$.

The most common utility functional in the literature is the constant elasticity of substitution utility functional

$$U[c] = \left(\int_I c(i)^{1-\gamma} di \right)^{\frac{1}{1-\gamma}}$$

Using our previous definitions a marginal change the variety distribution by ζ will lead to a change in utility given by Gâteaux differential

$$D_{\zeta(\cdot)} U[c] = \int_I \frac{\delta U[c]}{\delta c(i)} \zeta(i) di, \text{ for any } i \in I$$

where the marginal utility of variety i is given by the Gâteaux derivative

$$\begin{aligned} \frac{\delta U[c]}{\delta c(i)} &= \frac{1}{1-\gamma} \left(\int_I c(i)^{1-\gamma} di \right)^{\frac{\gamma}{1-\gamma}} (1-\gamma) c(i)^{-\gamma} \\ &= U[c]^\gamma c(i)^{-\gamma} \end{aligned}$$

For a specific variety $i = \iota$, the marginal utility can be represented by the Gâteaux derivative for a perturbation $\delta(i - \iota)$, that is

$$\frac{\delta U[c]}{\delta c(\iota)} = U[c]^\gamma c(\iota)^{-\gamma}, \text{ for } i = \iota \in I,$$

which allows us to determine the marginal rate of substitution between varieties i_1 and i_2 by

$$MRS_{i_0, i_1} = \left(\frac{c(i_0)}{c(i_1)} \right)^{-\gamma}, \text{ for any } i_0, i_1 \in I.$$

7.3.3 Infinite-dimensional production functions

Let $x(i)$ be the quantity of good of varieties $i \in I \subseteq [0, \infty)$. We denote x_j the quantity of variety $j \in I$. We can see $x(j) = \int_I \delta(i - j) q(i) di$. We denote x a variety distribution $x = (x(i))_I$. The set of variety distributions belong to the function space \mathcal{X} .

A production function is a functional $F[x]$ which maps the variety distribution into real production, a non-negative number, i.e. $F : \mathcal{X} \rightarrow \mathbb{R}_+$. We can write it as

$$y = F[x].$$

There are several production functions used in the literature (see, for instance, Parenti et al. (2017) and Bucci and Ushchev (2016)):

- the generalized AK production function

$$F[x] = \int_I A(i) x(i) di;$$

in which $A(i)$ is the specific marginal productivity of input $i \in I$,

- the generalized constant elasticity of substitution production function

$$F[x] = \left(\int_I A(i) x(i)^{\frac{\epsilon-1}{\epsilon}} di \right)^{\frac{\epsilon}{\epsilon-1}}$$

which is the infinite-dimensional analog of

$$F(\{x\}) = \left(\sum_{i \in I} A_i x_i^{\frac{\epsilon-1}{\epsilon}} \right)^{\frac{\epsilon}{\epsilon-1}},$$

where $I = \{i_1, \dots, i_n\}$;

- the O-ring production function (see Kremer (1993))

$$F[x] = \exp \left(\int_I \gamma(i) \log(x(i)) di \right)$$

where $\int_I \gamma(i) = 1$. This function is the infinite-dimensional of the finite-dimensional analog

$$F(\{x\}) = \prod_{i \in I} x_i^{\gamma_i}$$

for $\sum_I \gamma_i = 1$;

- the translog production function

$$F[x] = \exp \left(\int_I \gamma(i) \log(x(i)) + \gamma(i) \log(x(i)^2) di \right).$$

7.3.4 In information theory and econometrics

In, according to some authors, one of the most influential paper in the XX century Shannon (1948) introduces a measure of information by entropy. Entropy is a the functional

$$H[f] = - \int_X f(x) \ln(f(x)) dx,$$

which is used in an information theoretic approach to econometrics (see Judge and Mittelhammer (2012)).

7.4 Problems involving functionals

7.4.1 Extremes of functionals

The function $y^* \in \mathcal{Y}$ is an extreme of functional $F[y]$ if the value of functional has the value $F[y^*]$ and any small arbitrary perturbation $\eta \in \mathcal{Y}$, will not deviate the functional from that value. That is locally we have

$$D_{\eta(\cdot)} F[y^*] = 0.$$

An extreme $y^* \in \mathcal{Y}$ is a maximum, only if, for an arbitrary perturbation η , such that $y = y^* + \varepsilon \eta$ we have $F[y^*] \geq F[y]$, and it is a minimum only if $F[y^*] \leq F[y]$.

From the generalized Taylor expansion in equation (7.5) a necessary condition of second order for a maximum is

$$D_{\eta(\cdot)}^2 F[y^*] \leq 0.$$

7.4.2 Maximum of functionals

Consider the problem: find $y \in \mathcal{Y}$ that solves the problem

$$\max_{y(\cdot)} F[y]$$

A necessary condition for a maximum is that the Gâteaux derivative of $F[y]$ satisfies

$$\frac{\delta F[y^*]}{\delta y(x)} = \left. \frac{\delta F[y]}{\delta y(x)} \right|_{y^*(x)} = 0$$

Proof: Assume we know the optimum $y^*(x)$. The objective functional evaluated at the optimum is $F[y^*]$, which is a number. Introducing an arbitrary perturbation $\eta(x) \in \mathcal{Y}$ at the optimum we obtain $y(x) = y^*(x) + \varepsilon \eta(x)$ which has the value $F[y] = F[y^* + \varepsilon \eta]$. If $y^*(x)$ is an optimum then we should have $F[y^*] \geq F[y]$. Expanding $F[y]$ in a neighborhood of the optimum we have

$$F[y] = F[y^*] + D_{\eta(\cdot)} F[y^*] \varepsilon + \frac{1}{2} D_{\eta(\cdot), \eta(\cdot)} F[y^*] \varepsilon^2 + o(\varepsilon^2)$$

If y^* is a maximum it satisfies $D_{\eta(\cdot), \eta(\cdot)} F[y^*] \leq 0$. Therefore we can have $F[y^*] \geq F[y]$ only if $D_{\eta(\cdot)} F[y^*] = 0$.

The Taylor expansion also allows us to find a sufficient condition. Assume that: first, the functional is concave in the sense that it satisfies the condition:

$$D_{\eta(\cdot)}^2 F[y] \leq 0, \text{ for any } y \in \mathcal{Y}$$

and, second, there is an element of \mathcal{Y} , $y^*(x)$ satisfying the condition $D_{\eta(\cdot)} F[y^*] = 0$. Then $y^*(x) \in \mathcal{Y}$ is a maximum.

7.4.3 Constrained maximum of functionals

In economics we are generally interested in problems define by the maximization of a functional depending on constraints. We next consider two types of problems which differ as regards the nature of their constraints: problems with functional constraints and problems with local constraints.

Problems with functional constraints

Consider the two functionals over function $y : X \rightarrow \mathbb{R}$ belonging to the set $y \in \mathcal{Y}$ of bounded functions:

$$\mathbb{W}[y] = \int_X F(y(x)) dx$$

and

$$\mathbb{T}[y] = \int_X G(y(x)) dx$$

The first problem is: find function $y(x) \in \mathcal{Y}$ that solves

$$\begin{aligned} \max_{y(\cdot)} \int_X F(y(x)) dx \\ \text{subject to} \end{aligned} \tag{P1}$$

$$\int_X G(y(x)) dx = 0$$

We can define a generalized Lagrangean functional

$$\mathbb{L}[y; \lambda] = \mathbb{W}[y] + \lambda \mathbb{T}[y]$$

where $\lambda \in \mathbb{R}$ is the Lagrange multiplier. WE can define a Lagrangean (function)

$$L(y(x), \lambda) \equiv F(y(x)) + \lambda G(y(x)).$$

Therefore the Lagrangean functional can be written as a parameterized (by λ) functional

$$\mathbb{L}[y; \lambda] = \int_X L(y(x), \lambda) dx.$$

The necessary conditions for an optimum $y^*(x)$ are

$$\begin{aligned} \frac{\delta \mathbb{L}[y; \lambda]}{\delta y(x)} \Big|_{y^*(x)} &= F'(y^*(x)) + \lambda G(y^*(x)) = 0 \\ \frac{\partial \mathbb{L}[y; \lambda]}{\partial \lambda} \Big|_{y^*(x)} &= \int_X G(y^*(x)) dx = 0, \end{aligned}$$

where the first condition features a Gâteaux derivative and the second a classical derivative.

Problems with local constraints

Now consider the problem

$$\begin{aligned} \max_{y(\cdot), z(\cdot)} \int_X F(y(x), z(x)) dx \\ \text{subject to} \end{aligned} \tag{P2}$$

$$G(y(x), z(x)) = 0, \text{ for all } x \in X.$$

While in problem (P1) we had one constraint, in this case we have an infinity of constraints. Therefore, we have to introduce a Lagrangean function $\lambda : X \rightarrow \mathbb{R}$ (instead of a Lagrange multiplier $\lambda \in \mathbb{R}$ as in the previous problem).

The Lagrangean functional is now

$$\mathbb{L}[y, z; \lambda] = \int_X F(y(x), z(x)) + \lambda(x)G(y(x), z(x))dx$$

The necessary condition for an extremum $(y^*(x), z^*(x))$ are

$$\begin{aligned} \frac{\delta \mathbb{L}^*}{\delta y(x)} &= F_y(y^*(x), z^*(x)) + \lambda(x) G_y(y^*(x), z^*(x)) = 0, \text{ for each } x \in X \\ \frac{\delta \mathbb{L}^*}{\delta z(x)} &= F_z(y^*(x), z^*(x)) + \lambda(x) G_z(y^*(x), z^*(x)) = 0, \text{ for each } x \in X \\ \frac{\delta \mathbb{L}^*}{\delta \lambda(x)} &= G(y^*(x), z^*(x)) = 0, \text{ for each } x \in X. \end{aligned}$$

7.4.4 Applications

Problem 1 find the continuous maximum entropy distribution with support $[a, b]$. That is, solve

$$\begin{aligned} \max_{f(\cdot)} \mathbb{H}[f] &= - \int_a^b f(x) \ln(f(x)) dx \text{ (entropy functional)} \\ \text{subject to} \\ \mathbb{G}[f] &= \int_a^b f(x) dx = 1 \text{ (functional constraint)} \end{aligned}$$

The Lagrangean functional is

$$\begin{aligned} \mathbb{L}[f] &= \int_a^b L(f(x), \lambda) dx = \\ &= \int_a^b -f(x) \ln(f(x)) - \lambda f(x) dx \end{aligned}$$

where λ is a Lagrange multiplier. The previously obtained the first-order conditions yield

$$\frac{\delta \mathbb{L}[f^*]}{\delta f(x)} = \frac{\partial L(f(x))}{\partial f} = -\ln(f(x)) - \lambda - 1 = 0$$

if and only if $f(x) = e^{-(1+\lambda)}$; and substituting in the constraint

$$\mathbb{G}[f] = \int_a^b e^{-(1+\lambda)} dx = 1$$

if and only if $e^{-(1+\lambda)} = \frac{1}{b-a}$. Therefore the maximum entropy distribution $f^*(x)$

$$f^*(x) = \frac{1}{b-a}$$

is a uniform distribution.

Problem 2⁸ find the continuous maximum entropy distribution with support $(-\infty, \infty)$ which such that average satisfies $\mathbb{E}[x] = \mu$ and the variance satisfies $\mathbb{E}[(x - \mu)^2] = \sigma^2$. Recall that

$$\begin{aligned}\mathbb{E}[x] &= \int_{-\infty}^{\infty} x f(x) dx \\ \mathbb{V}[x] &= \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx\end{aligned}$$

The problem is: find $f(x)$ which solves the problem

$$\begin{aligned}\max_{f(\cdot)} \mathbb{H}[f] &= - \int_a^b f(x) \ln(f(x)) dx \text{ (entropy functional)} \\ \text{subject to} \\ \int_{-\infty}^{\infty} f(x) dx &= 1 \text{ (} f \text{ is a density function)} \\ \int_{-\infty}^{\infty} x f(x) dx &= \mu \text{ (with average equal to } \mu) \\ \int_{-\infty}^{\infty} x^2 f(x) dx &= \sigma^2 + \mu^2 \text{ (with variance equal to } \sigma^2).\end{aligned}$$

The last restriction is equivalent to $\mathbb{V}[x] = \sigma^2$, because

$$\mathbb{V}[x] = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx = \int_{-\infty}^{\infty} x^2 f(x) dx - 2 \int_{-\infty}^{\infty} \mu x f(x) dx + \int_{-\infty}^{\infty} \mu^2 f(x) dx = \int_{-\infty}^{\infty} x^2 f(x) dx - \mu^2.$$

The Lagrangean functional is

$$\begin{aligned}\mathbb{L}[f] &= \int_a^b L(x, f(x)) dx = \\ &= \int_a^b -f(x) \ln(f(x)) - \lambda_0 f(x) - \lambda_1 x f(x) - \lambda_2 x^2 f(x) dx\end{aligned}$$

where λ_0 , λ_1 and λ_2 are Lagrange multipliers (they are all numbers).

The first order condition is

$$\frac{\delta \mathbb{L}[f^*]}{\delta f(x)} = -\ln(f(x)) - 1 - \lambda_0 - \lambda_1 x - \lambda_2 x^2 = 0$$

Therefore

$$f(x) = e^{-(1 + \lambda_0 + \lambda_1 x + \lambda_2 x^2)}$$

There are two ways of finding the solution:

⁸See (Shannon, 1948, p.36), or (Cover and Thomas, 2006, ch. 12)

1. First approach: conjecture that the solution is a Gaussian integral

$$g(x) = ae^{-\frac{(x-b)^2}{2c^2}}$$

where a , b , and c are undetermined coefficients, and should be c a real and positive number. If the conjecture on the general form of the solution is correct, then we can obtain the three parameters by substituting this function in the three constraints. Fortunately, this is the case because we obtain a system of three equations in the three unknowns a , b , and c :

$$\begin{aligned}\int_{-\infty}^{\infty} g(x)dx &= a\sqrt{2\pi c} \\ \int_{-\infty}^{\infty} xg(x)dx &= ba\sqrt{2\pi c} \\ \int_{-\infty}^{\infty} x^2g(x)dx &= a\sqrt{2\pi c}(b^2 + c)\end{aligned}$$

Solving the system yields

$$a = \frac{1}{2\pi\sigma^2}, \quad b = \mu, \quad \text{and} \quad c = \sigma^2,$$

which implies that function $g(x)$ becomes

$$g(x) = e^{\log(a) - \frac{1}{2\sigma^2}(x^2 - 2bx + b^2)}.$$

Matching the exponent with $f(x)$, we find the Lagrange multipliers

$$\lambda_0 = -1 - \ln(2\pi\sigma^2)^{-\frac{1}{2}} + \frac{\mu^2}{2\sigma^2}, \quad \lambda_1 = -\frac{\mu}{\sigma^2}, \quad \lambda_2 = \frac{1}{2\sigma^2}.$$

2. Second approach: alternatively, we can substitute our candidate solution in the constraints and try to determine the Lagrange multipliers. Assuming that $\text{Re}(\lambda_2) > 0$, we find

$$\begin{aligned}\int_{-\infty}^{\infty} f(x)dx &= \sqrt{\frac{\pi}{\lambda_2}} e^{-1 - \lambda_0 + \frac{\lambda_1^2}{4\lambda_2}} = 1 \\ \int_{-\infty}^{\infty} xf(x)dx &= -\frac{\lambda_1}{2\lambda_2} \int_{-\infty}^{\infty} f(x)dx = \mu \\ \int_{-\infty}^{\infty} x^2f(x)dx &= \left(\frac{\lambda_1^2 + 2\lambda_2}{(2\lambda_2)^2}\right) \int_{-\infty}^{\infty} f(x)dx = \sigma^2 + \mu^2.\end{aligned}$$

If we solve for the Lagrange multipliers we obtain the same result

The optimal density function is the Normal distribution:

$$f^*(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$

Intuition: the problem is assume we have an unknown distribution which is required to have an average equal to μ and a variance equal to σ^2 , two known numbers, what is this distribution if we require the principle of maximum entropy to apply ? The answer is: the normal distribution.

7.4.5 Applications to the consumer problem

The optimal choice of varieties

Assume we have a continuum of varieties $I \in [0, \infty)$ and a basket of consumption containing different varieties is $C = (c(i))_{i \in I}$ where $c(i) \geq 0$ is the quantity of variety $i \in I$ in basket C . The composition of the basket can be seen as a function mapping between the space of varieties and a real number, the quantity consumed: $c : I \rightarrow \mathbb{R}_+$, belonging to a space of positively-valued bounded functions, $c \in \mathcal{C}$.

The value of the basket is measured by the utility functional $U : \mathcal{C} \rightarrow \mathbb{R}$:

$$U[c] = \left(\int_I c(i)^{1-\gamma} di \right)^{\frac{1}{1-\gamma}}.$$

The consumer has income $y > 0$ which can be spent on the purchase of baskets. The total expenditure is the functional

$$E[c] = \int_I p(i) c(i) di$$

where $p(\cdot)$ is the relative price of variety relative to the income deflator. The budget constraint is $E[p, c] = y$, assuming that the consumer has no savings.

The consumer problem is to find the basket $(c(i))_{i \in I}$ that solves the problem

$$\begin{aligned} \max_{c(\cdot)} U[c] &= \left(\int_I c(i)^{1-\gamma} di \right)^{\frac{1}{1-\gamma}} \\ &\text{subject to} \\ E[c] &= \int_I p(i) c(i) di = y. \end{aligned}$$

The Lagrangean functional can be interpreted as the indirect utility functional

$$\begin{aligned} L[c; \lambda] &= U[c] - \lambda E[c] \\ &= \left(\int_I c(i)^{1-\gamma} di \right)^{\frac{1}{1-\gamma}} - \lambda \int_I p(i) c(i) di \end{aligned}$$

The first order conditions are

$$\begin{aligned} \frac{\delta L[c^*]}{\delta c(i)} &= \frac{\delta U[c^*]}{\delta c(i)} - \lambda \frac{\delta E[c^*]}{\delta c(i)} = 0 \\ E[c^*] &= y. \end{aligned}$$

The first condition is equivalent to

$$\left(\frac{c(i)}{U[c]} \right)^{-\gamma} = \lambda p(i) \iff c(i) = U[c] \left(\lambda p(i) \right)^{-\frac{1}{\gamma}}.$$

Substituting in the utility functional

$$U[c] = \left(\int_I \left(U[c] \left(\lambda p(i) \right)^{-\frac{1}{\gamma}} \right)^{1-\gamma} di \right)^{\frac{1}{1-\gamma}}$$

allows us to find λ as

$$\frac{1}{\lambda} = P \equiv \left(\int_I p(i)^{\frac{\gamma-1}{\gamma}} \right)^{\frac{\gamma}{\gamma-1}},$$

that we interpret as the consumer price deflator (or the true index of cost of living) using as numéraire the income deflator. Substituting in the constraint and simplifying yields $P U[c] = y$. Substituting again in the expression for $c(i)$ yields the solution to the consumer problem as the basket $(c^*(i))_{i \in I}$ where

$$c^* = \frac{y}{P} \left(\frac{P}{p(i)} \right)^{\frac{1}{\gamma}}, \text{ for each } i \in I.$$

Therefore, the demand for every variety is proportional to income, and the is negatively related to the price-elasticity of demand, which is homogenous among varieties and is equal to $1/\gamma$, because

$$\frac{\partial \ln c^*(i)}{\partial \ln p(i)} = -\frac{1}{\gamma} < 0.$$

7.4.6 Application to production theory

This problem is a component of most neo-Keynesian models, as the problem for a final producer using a continuum of inputs $X = (x(i))_{i \in I}$. When bundles of inputs are Infinite-dimensional, as our X , models usually consider they refer to intermediary goods not factors of production.

Total sales in a competitive sales market $S(p, y) = py$ where p is the final good price and y is the output. Assume that the firm has a generalized constant elasticity of substitution (CES) production function

$$y = F[x] \equiv \left(\int_I A(i) x(i)^{\frac{\epsilon-1}{\epsilon}} di \right)^{\frac{\epsilon}{\epsilon-1}}$$

with specific factor productivity $A(i)$. Therefore, nominal sales are a functional

$$S[x] = p F[x],$$

where p is the price of the output. The total cost is also a functional

$$C[x] = \int_I w(i) x(i) di,$$

where $w(i)$ denotes the price of input $i \in I$. We can denote by $A = (A(i))_{i \in I}$ and $w = (w(i))_{i \in I}$ the profiles of productivity and costs associated to the input profile $x = (x(i))_{i \in I}$.

Therefore, firms profits are also a functional over the x

$$\Pi[x] = p F[x] - C[x].$$

Assuming a price-taker firm in all the markets, both the in the product market and the I markets for inputs, the firm's problem is to find the optimal input bundle $X^* = (x^*)_{i \in I}$ that solves the problem

$$\begin{aligned} \max_{x(\cdot)} \Pi[x] &= p \left(\int_I A(i) x(i)^{\frac{\epsilon-1}{\epsilon}} di \right)^{\frac{\epsilon}{\epsilon-1}} - \int_I w(i) x(i) di \\ \text{subject to} \\ \left(\int_I A(i) x(i)^{\frac{\epsilon-1}{\epsilon}} di \right)^{\frac{\epsilon}{\epsilon-1}} &= d \end{aligned}$$

where d is the market demand. In equilibrium $y = F[x] = d$.

Exercise: Prove that the solution is

$$x^*(i) = \left(\frac{W A(i)}{w(i)} \right)^\epsilon y, \text{ for each } i \in I$$

where $W = W[A, w] \equiv \left(\int_I A(i)^\epsilon w(i)^{1-\epsilon} di \right)^{\frac{1}{1-\epsilon}}$ is a measure of the aggregate marginal costs.

7.4.7 Optimal taxation

Let $\theta \in \Theta \subseteq \mathbb{R}_+$ denote the skill level of the population and let $f(\theta)$ be their density. Therefore $\int_\Theta f(\theta) d\theta = 1$. Let $\ell(\theta)$, $y(\theta) = \theta \ell(\theta)$, and $c(\theta)$ the work effort, the income and consumption by people of skill level θ . The utility for a household with skill level θ is $u(\theta) = U(c(\theta), \ell(\theta))$.

Assume the government has an exogenous expenditure level G and wants to find an optimal tax schedule $T(\theta) = \tau(\theta) y(\theta)$ which implements a social optimum. Assume that the social optimal criterium is the average social welfare

$$W[u] = \int_\Theta W(u(\theta)) f(\theta) d\theta.$$

Assume that the central planner not only observes the distribution of income $y(\theta) = \theta \ell(\theta)$ but has also complete information on the work effort, that is it is able to separate the productivity θ from the work effort $\ell(\theta)$.

The problem is simpler if we use the implicit function theorem to solve $u(\theta) = U(c(\theta), \ell(\theta))$ for $c(\theta) = C(u(\theta), \ell(\theta))$.

We can find the optimal allocation of utility and work effort by solving the functional problem

$$\begin{aligned} \max_{u(\cdot), \ell(\cdot)} \int_\Theta W(u(\theta)) f(\theta) d\theta \\ \text{subject to} \\ \int_\Theta \left(\theta \ell(\theta) - C(u(\theta), \ell(\theta)) \right) f(\theta) d\theta = G \end{aligned}$$

If we can find c^* and ℓ^* then the optimal optimal tax-transfer policy that implements the social optimum, and finances the government expenditure G , has the following property

$$T^*(\theta) = y^* - c^*.$$

Chapter 8

Introduction to optimal control: the maximum principle approach

8.1 Introduction

The Pontryagin's maximum principle (PMP), see Pontryagin et al. (1962), provides first order necessary conditions for the optimal control problem, from a slightly different approach than the Calculus of Variations approach. Although the two approaches lead to the same solution for when applied to the same simple problems, the PMP can be more flexible when dealing with some type of problems (singular problems, for instance). As we will see that the first-order conditions are a system of two ordinary differential equations (and not an implicit second order ODE) it allows a more direct use of results from the theory of ODE's, and also to use geometrical methods when the constitutive functions of the problem are not completely specified or the first-order conditions do not have explicit solutions.

In this chapter we consider the same cases as we did in the calculus of variations chapter.

We denote again the independent variable by x and assume it has the domain $X \subseteq \mathbb{R}$. We can write $X = [x_0, x_1]$ if it is a closed set, or $X = (x_0, x_1)$ if it is open, where $x_0 < x_1$ are fixed or determined optimally, and x_1 can be bounded or unbounded. In problems in which time is the independent variable we use instead t as the independent variable and $T \subseteq \mathbb{R}_+$ as its domain, and we usually set $t_0 = 0$.

The optimal control problem has two variables we need to find: the **state variable**, denoted by $y(x)$ (or $y(t)$) and the **control variable**, denoted by $u(x)$ (or $u(t)$ in the time-domain). As we consider only problems in which the state variable is of dimension one, the state variable is a mapping $y : X \rightarrow Y \subseteq \mathbb{R}$ and the control variable is a mapping $u : X \rightarrow U \subseteq \mathbb{R}^m$. That is, we may have more m control variables. Again it is important to distinguish between the **point-wise level** of variables, i.e $y(x')$ and $u(x')$ $x = x'$, from the **curves traced out in the range of variables** $(y(x))_{x \in X}$ and $(u(x))_{x \in X}$, or **paths or trajectories** if the time-domain $(y(t))_{t \in T}$ and

$$(u(t))_{t \in T}.$$

A solution to an optimal control problem allows for finding optimal curves (optimal trajectories), traced out in the specified or optimized domain, (or time interval) according to one criterium (a functional) and given some constraints. The constraints can be specified point-wise for all the domain of the independent variable, can be specified in particular points (usually boundary points in X or T), or for all the domain (we will see this case in the next chapter).

If we can find an optimality criterium for the pointwise behavior of the state and control variables, say functions $y^*(x)$ and $u^*(x)$ for every $x \in X$ (or $y^*(t)$ and $u^*(t)$ for every $t \in T$) then we can trace-out the optimal curves $(y^*(x))_{x \in X}$ and $(u^*(x))_{x \in X}$.

From now on we denote the curves by $y \equiv (y(x))_{x \in X}$ and $u \equiv (u(x))_{x \in X}$.

The optimal control problem consists in finding functions $y \in \mathcal{Y}$ and $u \in \mathcal{U}$, where $\mathcal{Y} \in C^1(\mathbb{R})$, the set of continuous and continuously differentiable functions $y : X \rightarrow \subseteq \mathbb{R}$, and $\mathcal{U} \in PC^1(\mathbb{R})$, the set of piecewise continuous functions $u : X \rightarrow U \subseteq \mathbb{R}^m$ such that

$$y' = G(y(x), u(x), x), \text{ for } x \in [x_0, x_1] \quad (8.1)$$

that maximize the functional

$$J[y, u] \equiv \int_{x_0}^{x_1} F(x, y(x), u(x)) dx \quad (8.2)$$

with additional data on the boundaries of sets X and Y . The additional data is related to the information concerning the boundary values of the independent variable x_0 and x_1 and/or the boundary values for the state variable $y(x_0)$ and $y(x_1)$.

In most applications in macroeconomics and growth theory the independent variable is time. In this case $x = t$ and $t \in T \subseteq \mathbb{R}_+$. In this case, the optimal control problem consists in finding functions $y \in \mathcal{Y}$ and $u \in \mathcal{U}$, where $\mathcal{Y} \in C^1(\mathbb{R})$, the set of continuous and continuously differentiable functions $y : X \rightarrow Y \subseteq \mathbb{R}$, and $\mathcal{U} \in PC^1(\mathbb{R})$, the set of piecewise continuous functions $u : X \rightarrow U \subseteq \mathbb{R}^m$ such that

$$\dot{y} = G(y(t), u(t), t), \text{ for } t \in [t_0, t_1] \quad (8.3)$$

that maximize the functional

$$J[y, u] \equiv \int_{t_0}^{t_1} F(t, y(t), u(t)) dt \quad (8.4)$$

with additional data is given. The additional data is related to the information concerning the boundary values of the independent variable t_0 and t_1 and the boundary values for the state variable $y(t_0)$ and $y(t_1)$.

The necessary conditions for an optimum according to the **Pontryagin's maximum principle** are set by using the **Hamiltonian** function, defined as

$$H(x, y, u, \lambda) = F(x, y, u) + \lambda G(x, y, u).$$

where λ , called the co-state variable, is a piecewise continuous mapping $\lambda : X \rightarrow \mathbb{R}$. When the independent variable is time, i.e, $X = T$, we write

$$H(t, y, u, \lambda) = F(t, y, u) + \lambda G(t, y, u).$$

where λ is a piecewise continuous function $\lambda : T \rightarrow \mathbb{R}$.

Next we present the optimality conditions for a bounded domain, not necessarily time, in section 8.2 and an example in section ???. Then we move to the time domain particular problems in section 8.3 and present several economic applications.

8.2 General domain problems

8.2.1 Constraints on the boundary values of the state variable

In this subsection we assume that the data of the problem includes the boundary values for the independent variable: i.e., x_0 and x_1 are known. The optimal control problem is to find an optimal control curve $(u^*(x))_{x \in [x_0, x_1]}$ that maximizes the functional (8.2) subject to ODE constraint (8.1) and, possibly additional information for the state variables at the boundary values for the independent variable.

In other words: the bounds of the domain X are known and the limits of the curves $y \in Y$, traced out by $y(x)$ for $x \in X$, may be known or may be chosen optimally.

Formally, the problem is

$$\begin{aligned} & \max_{u(\cdot)} \int_{x_0}^{x_1} F(x, y(x), u(x)) dx \\ & \text{subject to} \\ & y' = G(y(x), u(x), x), \text{ for } x \in [x_0, x_1] \\ & x_0 \text{ and } x_1 \text{ given} \\ & \text{conditions on } y(x_0) \text{ and } y(x_1) \end{aligned} \tag{P1}$$

We can consider the following cases:

- (a) both boundary values are known: $y(x_0) = y_0$ and $y(x_1) = y_1$ fixed; (P1a)
- (b) the lower boundary value is known: $y(x_0) = y_0$ fixed and $y(x_1)$ free; (P1b)
- (c) the upper boundary value is known: $y(x_0)$ free and $y(x_1) = y_1$ fixed; (P1c)
- (d) both boundary values are free: $y(x_0)$ and $y(x_1)$ free; (P1d)

Proposition 1. [*First order necessary conditions for fixed boundary values of the independent variable*] Let (y^*, u^*) be a solution (curve) to the OC problem (P1) in which one of

the conditions (P1a), or (P1b), or (P1c) or (P1d) is introduced. Then there is a piecewise continuous function $\lambda : [x_0, x_1] \rightarrow \mathbb{R}$, called co-state variable, such that the curves (y^*, u^*, λ) satisfy the following conditions:

- the optimality condition ¹:

$$H_u(x, y^*(x), u^*(x), \lambda(x)) = 0, \text{ for each } x \in [x_0, x_1] \quad (8.6)$$

- the multiplier equation

$$\lambda' = -H_y(x, y^*(x), u^*(x), \lambda(x)), \text{ for each } x \in (x_0, x_1) \quad (8.7)$$

- the constraint of the problem:

$$y^{*'} = G(x, y^*(x), u^*(x)), \text{ for each } x \in (x_0, x_1) \quad (8.8)$$

- and the adjoint conditions associated to the boundary conditions (P1a) to (P1d)

- for problem (P1a)

$$y^*(x_0) = y_0 \text{ for } x = x_0, \text{ and } y^*(x_1) = y_1 \text{ for } x = x_1, \quad (8.9)$$

- for problem (P1b)

$$y^*(x_0) = y_0 \text{ for } x = x_0, \text{ and } \lambda(x_1) = 0 \text{ for } x = x_1, \quad (8.10)$$

- for problem (P1c)

$$\lambda(x_0) = 0 \text{ for } x = x_0, \text{ and } y^*(x_1) = y_1 \text{ for } x = x_1, \quad (8.11)$$

- for problem (P1d)

$$\lambda(x_0) = 0 \text{ for } x = x_0, \text{ and } \lambda(x_1) = 0 \text{ for } x = x_1. \quad (8.12)$$

Proof. (Heuristic) Let $u^* = (u^*(x))_{x \in X}$ be an optimal control curve and let $y^* = (y^*(x))_{x \in X}$ be the associated state curve. The value of the problem is

$$J[y^*, u^*] = \int_{x_0}^{x_1} F(x, y^*(x), u^*(x)) dx.$$

It is an optimiser if $J[y^*, u^*] \geq J[y, u]$ is satisfied for any other admissible pair of functions $(u(x), y(x))$.

¹We use the notation $H_u(x, y(x), u(x), \lambda(x)) \equiv \frac{\partial H(x, y(x), u(x), \lambda(x))}{\partial u}$ is the derivative evaluated at point $x \in X$ for any curves (y, u, λ) and $H_u(x, y^*(x), u^*(x), \lambda(x))$ is the derivative evaluated for the optimal curves (y^*, u^*) . The derivatives for y are denoted in analogous way.

It is convenient to write

$$\begin{aligned}
J[y^*, u^*] &= \int_{x_0}^{x_1} F(x, y^*(x), u^*(x)) dx = \\
&= \int_{x_0}^{x_1} \left[F(x, y^*(x), u^*(x)) + \lambda(x)(G(x, y^*(x), u^*(x)) - y^{*\prime}(x)) \right] dx = \\
&= \int_{x_0}^{x_1} \left[H(x, y^*(x), u^*(x), \lambda(x)) - y^{*\prime}(x)\lambda(x) \right] dx
\end{aligned}$$

Again we introduce a perturbation on the optimal state-control pair $(y, u) = (y^*, u^*) + \varepsilon \boldsymbol{\eta}$, where ε is a constant and $\boldsymbol{\eta} = (\eta_y, \eta_u)$. The admissible perturbations differ for the different versions of the problem: for (P1a) we should have $\eta_y(x_0) = \eta_y(x_1) = 0$, for (P1b) we should have $\eta_y(x_0) = 0$ and $\eta_y(x_1) \neq 0$, for (P1c) we should have $\eta_y(x_0) \neq 0$ and $\eta_y(x_1) = 0$, and for (P1d) we should have $\eta_y(x_0) \neq 0$ and $\eta_y(x_1) \neq 0$.

The first-order Taylor approximation of the functional is

$$J[y, u] = J[y^*, u^*] + \delta J[y^*, u^*](\boldsymbol{\eta})\varepsilon + o(\varepsilon)$$

where

$$\begin{aligned}
\delta_{\boldsymbol{\eta}(\cdot)} J[y^*, u^*](\boldsymbol{\eta}) &= \int_{x_0}^{x_1} \left\{ H_u(x, y^*(x), u^*(x), \lambda(x)) \eta_u(x) + H_y(x, y^*(x), u^*(x), \lambda(x)) \eta_y(x) - \lambda(x) \eta_y'(x) \right\} dx = \\
&= \int_{x_0}^{x_1} \left\{ H_u(x, y^*(x), u^*(x), \lambda(x)) \eta_u(x) + (H_y(x, y^*(x), u^*(x), \lambda(x)) + \lambda'(x)) \eta_y(x) \right\} dx + \\
&+ \lambda(x_0) \eta_y(x_0) - \lambda(x_1) \eta_y(x_1).
\end{aligned}$$

Then $J[y, u] \leq J[y^*, u^*]$ only if $\delta_{\boldsymbol{\eta}(\cdot)} J[y^*, u^*](\boldsymbol{\eta}) = 0$, which, using similar arguments as in the case of the calculus of variations problem, is equivalent to the Pontryagin's conditions: $H_u(\cdot) = \lambda' - H_y(\cdot) = 0$. The adjoint constraints should verify $\lambda(x_0)\eta_y(x_0) = \lambda(x_1)\eta_y(x_1) = 0$. From this and the admissibility values for $\eta_y(x_0)$ and $\eta_y(x_1)$ then the adjoint constraints are as in equations (8.9) to (8.12) \square

8.2.2 Constraints on the boundary values of the independent variable

In this subsection we consider the case in which one or both bounds in the domain of independent variables can be optimally chosen, i.e $x \in X^* = [x_0^*, x_1^*]$, where one or both x_j^* , for $j = 0, 1$ are free, but the boundary values for the state variable are fixed: i.e. $y(x_0^*) = y_0$ and/or $y(x_1^*) = y_1$ are fixed. The optimal control problem is to find the optimal cut-off values for the independent variable, x_0^* and/or x_1^* and an optimal control $(u^*(x))_{x \in [x_0^*, x_1^*]}$ that maximizes the functional (8.2) subject to ODE constraint (8.1).

In other words: the bounds of the domain X^* can be known or can be chosen optimally while the limits of the curves $y \in Y$, traced out by $y(x)$ for $x \in X^*$ are known.

Formally, the problem is

$$\begin{aligned}
& \max_{u(\cdot)} \int_{x_0}^{x_1} F(x, y(x), u(x)) dx \\
& \text{subject to} \\
& y' = G(y(x), u(x), x), \text{ for } x \in [x_0, x_1] \\
& y(x_0) = y_0 \text{ and } y(x_1) = x_1 \text{ given} \\
& \text{conditions on } x_0 \text{ and } x_1
\end{aligned} \tag{P2}$$

We can consider the following cases:

$$(a) \text{ both cut-offs are known: } x_0 \text{ and } x_1 \text{ fixed;} \tag{P2a}$$

$$(b) \text{ the lower cut-off is known: } x_0 \text{ fixed and } x_1 \text{ free;} \tag{P2b}$$

$$(c) \text{ the upper cut-off is known: } x_1 \text{ free and } x_0 \text{ fixed;} \tag{P2c}$$

$$(d) \text{ both cut-offs are free: } x_0 \text{ and } x_1 \text{ free;} . \tag{P2d}$$

Proposition 2 (First order necessary conditions for free domain and fixed boundary state variable optimal control problems). *Let (y^*, u^*) be a solution curve to the OC problem (P2) where $y(x_0) = y_0$ and $y(x_1) = y_1$ are fixed. Then there is an optimal domain for the independent variable $x^* = [x_0^*, x_1^*] \subset \mathbb{R}$, a piecewise continuous function $\lambda : x^* \rightarrow \mathbb{R}$, called co-state variable, such that (y^*, u^*, λ) satisfy the optimality condition (8.6), the multiplier equation (8.7) and the ODE constraint of the problem (8.8), all for $x \in \text{Int}(X^*)$ and the adjoint conditions associated to the boundary conditions (P2a) to (P2d)*

- for problem (P2a) $y^*(x_0) = y_0$ and $y^*(x_1^*) = y_1$ and x_0 and x_1 are fixed;

- for problem (P2b) $y^*(x_0) = y_0$ and $y^*(x_1^*) = y_1$ and

$$x_0^* = x_0 \text{ and } H(x_1^*, y_1, u^*(x_1^*)) - y^{*'}(x_1^*)\lambda(x_1^*) = 0; \tag{8.14}$$

- for problem (P2c) $y^*(x_0^*) = y_0$ and $y^*(x_1) = y_1$ and

$$H(x_0^*, y_0, u^*(x_0^*)) - y^{*'}(x_0^*)\lambda(x_0^*) = 0 \text{ and } x_1^* = x_1; \tag{8.15}$$

- for problem (P2d) $y^*(x_0^*) = y_0$ and $y^*(x_1^*) = y_1$ and

$$H(x_0^*, y_0, u^*(x_0^*)) - y^{*'}(x_0^*)\lambda(x_0^*) = 0 \text{ and } H(x_1^*, y_1, u^*(x_1^*)) - y^{*'}(x_1^*)\lambda(x_1^*) = 0. \tag{8.16}$$

Proof. Using the same method for finding perturbations we used in the proof of propositions ?? and 1, the Gâteaux derivative of the value functional,

$$\begin{aligned}
\delta_{(\eta(\cdot), \chi)} J[y^*, u^*; x^*] &= \int_{x_0^*}^{x_1^*} (H_u(x, y^*(x), u^*(x), \lambda(x))\eta_u(x) + H_y(x, y^*(x), u^*(x), \lambda(x))\eta_y(x) - \lambda(x)\eta_y'(x)) dx + \\
&+ H(x, y^*(x), u^*(x), \lambda(x))|_{x=x_1^*} \chi_1 - H(x, y^*(x), u^*(x), \lambda(x))|_{x=x_0^*} \chi_0,
\end{aligned}$$

recall that we introduced the perturbation $x_j = x_j^* + \varepsilon \chi_j$ for $j \in \{0, 1\}$. Setting $H^*(x) = H(x, y^*(x), u^*(x), \lambda(x))$, integrating by parts,

$$\begin{aligned} \delta_{(\eta(\cdot), \chi)} J[y^*, u^*; x^*] &= \int_{x_0^*}^{x_1^*} (H_u^*(x) \eta_u(x) + (H_y^*(x) + \lambda'(x)) \eta_y(x)) dt + \lambda(x_0^*) \eta_y(x_0^*) - \lambda(x_1^*) \eta_y(x_1^*) + \\ &+ H^*(x_1^*) \chi_1 - H^*(x_0^*) \chi_0. \end{aligned}$$

Using the same approximation as in the proof of Proposition ?? yields the analogue to equation (??)

$$\begin{aligned} \delta J[y^*, u^*; x^*] (\eta, \chi) &= \int_{x_0^*}^{x_1^*} (H_u^*(x) \eta_u(x) + (H_y^*(x) + \lambda'(x)) \eta_y(x)) dt + \lambda(x_0^*) \eta_0 - \lambda(x_1^*) \eta_1 + \\ &+ (H^*(x_1^*) - y^{*'}(x_1^*) \lambda(x_1^*)) \chi_1 - (H^*(x_0^*) - y^{*'}(x_0^*) \lambda(x_0^*)) \chi_0 \end{aligned} \quad (8.17)$$

The adjoint necessary conditions for the optimum, because $\eta_1 = \eta_0 = 0$, are presented, for the different versions of the problem, in equations (8.14) to (8.16). \square

8.2.3 A taxonomy for optimal control problems

This is a general case that encompasses combinations of all the previous cases: we assume both the domains of the independent variables and the boundary values of the state variables are free. That is x_0 and/or x_1 can be fixed or free and $y(x_0)$ and/or $y(x_1)$ can be fixed or free.

When there is a free boundary condition, for the independent variable x or for the state variable $y(x)$, it should be optimized. In the first case, the optimal control problem is to find the optimal cut-off values for the independent variable, x_0^* and/or x_1^* and an optimal control $(u^*(x))_{t \in [x_0^*, x_1^*]}$ that maximizes the functional (8.2) subject to ODE constraint (??) and having fixed or free boundary values for the state variable. In the second case, the optimal control problem is to find the optimal boundary values for the state variable, $y^*(x_0)$ and/or $y^*(x_1)$ and an optimal control $(u^*(x))_{t \in [x_0, x_1]}$ that maximizes the functional (8.2) subject to ODE constraint (??) and having fixed or free cut-off values for the independent variable.

The necessary conditions include the optimality condition (8.6), the multiplier equation (8.7) and the ODE constraint of the problem (8.8), all for $x \in \text{int}(x^*)$. To get the adjoint condition associated to the terminal values of the state variable, when they need to be optimized, are obtained by setting in equation (8.17), $\eta_0 \neq 0$ and $\eta_1 \neq 0$. Therefore, the adjoint condition associated to $y^*(x_j^*)$ and $\lambda(x_j^*) = 0$, implying that the adjoint condition associated to the optimal boundary value of the independent variable, x_j^* is $H^*(x_j^*) = 0$, for $j = 0, 1$.

The adjoint conditions presented in Table 8.1 cover the 16 possible cases and it is the analogue to Table ?? for the calculus of variations problem.

Table 8.1: Adjoint conditions for bounded domain OC problems

data		optimum	
x_j	$y(x_j)$	x_j^*	$y^*(x_j^*)$
fixed	fixed	x_j	y_j
fixed	free	x_j	$\lambda(x_j) = 0$
free	fixed	$H(x_j^*, y_j, u^*(x_j^*)) - y^{*'}(x_j^*)\lambda(x_j^*) = 0$	y_j
free	free	$H(x_j^*, y^*(x_j^*), u^*(x_j^*)) = 0$	$\lambda(x_j^*) = 0$

The index refers to the lower boundary when $j = 0$ and to the upper boundary when $j = 1$

8.3 Time domain problems

Next we present two problems which are common when the independent variable is time: the constrained terminal state problem and the discounted infinite horizon problem. While the second is typical from time-domain problems, the first can also occur in general x -domain problems. If this is the case we can simply adapt the results from the previous section.

In both problem we take already presented objective functional and dynamic constraint, in equations (8.4) and (8.3.1), respectively.

8.3.1 Constrained terminal state problem

A common problem in macroeconomics is the following: the set of independent variables is known such as $t_0 = 0$ and $t_1 = \bar{t}$, the initial value of the state value is fixed, $y(0) = y_0$, the structure of the economy given by the ODE (8.4), the value functional is , and we assume that the terminal value for the state variable is constrained by $R(\bar{t}, y(\bar{t})) \geq 0$ where $y(\bar{t})$ is free. Our goal is to determine the optimal trajectories for the state variable $y^* (y^*(t))_{t \in T}$ and the $u^* (u^*(t))_{t \in T}$.

Formally the problem is

$$\begin{aligned}
 & \max_{u(\cdot)} \int_0^{\bar{t}} F(t, u(t), y(t)) dt \\
 & \text{subject to} \\
 & \dot{y} = G(t, u(t), y), \text{ for } t \in T \\
 & \bar{t} \text{ given} \\
 & y(0) = y_0 \text{ fixed} \\
 & R(\bar{t}, y(\bar{t})) \geq 0,
 \end{aligned} \tag{Pt1}$$

where $T = [0, \bar{t}]$ and functions $R(\cdot)$, $F(\cdot)$, and $G(\cdot)$ are known.

The Hamiltonian function is

$$H(t) = H(t, u, y, \lambda) \equiv F(t, u, y) + \lambda G(t, u, y), \text{ for } t \in T$$

where λ is called co-state (or adjoint) and is a piecewise continuous function $\lambda : T \rightarrow \mathbb{R}$. We

assume H to be continuous, and continuously differentiable, and except otherwise mentioned that $H_{uu}(t) \neq 0$ for every $t \in T$.

Proposition 3. 1st order necessary conditions for the constrained terminal value problem Let (y^*, u^*) be the solution trajectories for problem Pt1. Then it satisfies

- the optimality condition

$$H_u(t, u^*(t), y^*(t), \lambda(t)) = 0, \text{ for each } t \in T; \quad (8.18)$$

- the multiplier equation

$$\dot{\lambda} = -H_y(t, u^*(t), y^*(t), \lambda(t)) = 0, \text{ for each } t \in T; \quad (8.19)$$

- the transversality condition

$$\lambda(\bar{t})R(\bar{t}, y^*(\bar{t})) = 0, \quad (8.20)$$

and the admissibility conditions:

$$\dot{y}^* = G(t, u^*(t), y^*(t)) = 0, \text{ for each } t \in T; \quad (8.21)$$

and

$$y^*(0) = y_0, \text{ for } t = 0 \quad (8.22)$$

Proof. In this case the value at the optimum is

$$J[y^*, u^*] = \int_0^{\bar{t}} (H(t, u^*(t), y^*(t), \lambda(t)) - \dot{y}^*(t)\lambda(t)) dt + \psi R(\bar{t}, y(\bar{t}))$$

where ψ is a Lagrange multiplier. The functional derivative, for an arbitrary perturbation $(\delta y, \delta u) = \varepsilon(\eta_y, \eta_u)$ around (y^*, u^*) , is now

$$\begin{aligned} \delta_{(\eta_y(\cdot), \eta_u(\cdot))} J[y^*, u^*] &= \int_0^{\bar{t}} [H_u(t, y^*(t), u^*(t), \lambda(t))\eta_u(t) + (H_y(t, y^*(t), u^*(t), \lambda(t)) + \dot{\lambda}(t))\eta_y(t)] dt + \\ &+ \lambda(0)\eta_y(0) + (\psi R_y(\bar{t}, y^*(\bar{t})) - \lambda(\bar{t}))\eta_y(\bar{t}), \end{aligned}$$

where admissible perturbations satisfy $\eta_y(0) = 0$ and $\eta_y(\bar{t}) \neq 0$. Given the inequality constraint, the KKT conditions

$$R(\bar{t}, y^*(\bar{t})) \geq 0, \quad \psi \geq 0, \quad \psi R(\bar{t}, y^*(\bar{t})) = 0,$$

are also necessary for an optimum. Setting $H_u^*(t) = \dot{\lambda}(t) - H_y^*(t) = \eta_y(0) = 0$, as presented in conditions (8.18)-(8.19). At last, because $\eta_y(\bar{t}) \neq 0$, the remaining necessary condition for an optimum is $\psi R_y(\bar{t}, y^*(\bar{t})) - \lambda(\bar{t}) = 0$. Multiplying both terms by $R(\bar{t}, y^*(\bar{t}))$ and using the KKT condition yields condition (8.20). \square

8.3.2 Infinite horizon problems

Necessary conditions for an optimum

The benchmark problem in macroeconomics and growth theory is the (autonomous) **discounted infinite horizon problem** is

$$\begin{aligned} \max_{u(\cdot)} \int_0^\infty e^{-\rho t} f(y(t), u(t)) dt \\ \text{subject to} \\ \dot{y} = g(y, u), \text{ for } t \in T \\ y(0) = y_0 \text{ fixed} \\ \text{boundary conditions at infinity.} \end{aligned} \tag{Pt2}$$

Two versions, related to different boundary conditions, are usually considered

$$\lim_{t \rightarrow \infty} y(t) \text{ is free} \tag{Pt2a}$$

$$\lim_{t \rightarrow \infty} R(t, y(t)) \geq 0 \tag{Pt2b}$$

where $\rho > 0$, and function $R(t, y)$ is known and takes the form of a solvability or sustainability condition. Observe that the utility function is $F(t, y(t), u(t)) \equiv e^{-\rho t} f(y(t), u(t))$ is directly dependent on time by a discount factor, which is a bounded function of time, and we consider a version of the problem in which the constraint ODE is autonomous.

For discounted optimal control problems define the **current-value Hamiltonian** function

$$\begin{aligned} h(y(t), u(t), q(t)) &= f(y(t), u(t)) + q(t) g(y(t), u(t)) = \\ &= e^{-\rho t} H(t, y(t), u(t), \lambda(t)). \end{aligned}$$

where $q(t) = e^{\rho t} \lambda(t)$ is the current-value co-state variable. Consistently with the previous definitions we call **discounted Hamiltonian** and **discounted co-state variable** to $H(t, y, u, \lambda)$ and λ , respectively. Again q (or λ) are piecewise continuous functions $q : T \rightarrow \mathbb{R}$ (or $\lambda : T \rightarrow \mathbb{R}$).

Observe the current-value Hamiltonian is time-independent. If the constraint is time-dependent, i.e, if $g(t, y, u)$ then Hamiltonian is also explicitly time dependent

$$h(t, y(t), u(t), q(t)) = f(y(t), u(t)) + q(t) g(t, y(t), u(t)).$$

Proposition 4 (First order necessary conditions: Pontryagin maximum principle). *Let (y^*, u^*) be the optimal state and control trajectory pair. Then there is a PC^1 continuous co-state variable q such that the following conditions hold:*

- the optimality condition

$$h_u(y^*(t), u^*(t), q(t)) = 0, \text{ for each } t \in [0, \infty) \tag{8.24}$$

- the multipliers equation for the current co-state variable (also called adjoint equation)

$$\dot{q} = \rho q - h_y(y^*(t), u^*(t), q(t)), \text{ for each } t \in [0, \infty) \quad (8.25)$$

- the transversality condition or (Pt2b):

– associated to (Pt2a)

$$\lim_{t \rightarrow \infty} e^{-\rho t} q(t) = 0, \quad (8.26)$$

– associated to (Pt2b)

$$\lim_{t \rightarrow \infty} e^{-\rho t} q(t) y^*(t) = 0; \quad (8.27)$$

- and the admissibility conditions

$$\dot{y}^* = g(y^*(t), u^*(t)), \text{ for each } t \in [0, \infty) \quad (8.28a)$$

$$y^*(0) = y_0, \text{ for } t = 0. \quad (8.28b)$$

Proof. We can see this proposition as a particular case of Propositions 1 and Proposition 3. \square

Remark: if the constraint ODE is non-autonomous, i.e. if $\dot{y} = g(t, y(t), u(t))$ equations (8.25) and (8.28a) will become non-autonomous ODE's, because the current value Hamiltonian becomes (directly) time-dependent, i.e. $h(t) = h(t, y(t), u(t), q(t)) = f(y(t), u(t)) + q(t) g(t, y(t), u(t))$.

Sufficient conditions for an optimum

The nature of the transversality condition (8.27) is a difficult technical issue associated with the solution to infinite-horizon optimal control problems (see Michel (1982) and Kamihigashi (2001)).

From now on, we assume the **Arrow sufficiency condition**: $h_{uu}^* = h(y^*, u^*, q) \leq 0$. This condition guarantees that the first-order necessary conditions for an extremum, presented in Proposition 4, are also necessary.

8.4 The dynamics of optimal control problems

The infinite-horizon discounted problem is the central structure to macroeconomics and growth theory since the 1960's.

In several applications the constitutive functions $f(y, u)$ and $g(y, u)$ are specified explicitly, or, if they have a non-linear structure the resulting system of ODE's usually cannot be solved explicitly. However, we can have a geometric interpretation for the solution of an optimal control problem in regular cases.

Writing

$$h(y, u, q) = f(y, u) + q g(y, u),$$

the necessary (and possibly sufficient as well) conditions for the infinite-horizon discounted optimal control problem, presented in Proposition 4, can be compactly presented as a differential-algebraic system:

$$\begin{aligned}\dot{y} &= g(y, u) \\ \dot{q} &= \rho q - h_y(y, u, q). \\ 0 &= h_u(y, u, q)\end{aligned}\tag{8.29}$$

Observe that $h_q(y, u, q) = g(y, u)$, $h_{qy}(y, u, q) = h_{yq}(y, u, q) = g_y(y, u)$, and $h_{qu}(y, u, q) = h_{uq}(y, u, q) = g_u(y, u)$.

The (local) existence and uniqueness of a steady state can be assessed from the Jacobian of system (8.29) evaluated at $\dot{y} = \dot{q} = 0$, that if

$$\mathbf{F}(y, u, q) = \begin{pmatrix} g_y(y, u) & g_u(y, u) & 0 \\ -h_{yy}(y, u, q) & -h_{uy}(y, u, q) & \rho - g_y(y, u) \\ h_{yu}(y, u, q) & h_{uu}(y, u, q) & g_u(y, u) \end{pmatrix}.$$

The determinant of \mathbf{F} is

$$\det(\mathbf{F})(y, u, q) = (g_y - \rho)(g_y h_{uu} - g_u h_{uy}) + g_u(g_u h_{yy} - g_y h_{yu})$$

where all the partial derivatives are evaluated at an arbitrary point (y, u, q) . As $h_{yy}(y, u, q) = f_{yy}(y, u) + q g_{yy}(y, u)$, and if the functions are continuous $h_{yu}(y, u, q) = h_{uy}(y, u, q) = f_{yu}(y, u) + q g_{yu}(y, u) = f_{uy}(y, u) + q g_{uy}(y, u)$ and $h_{uu}(y, u, q) = f_{uu}(y, u) + q g_{uu}(y, u)$, we readily see that:

1. if $f(y, u)$ and $g(y, u)$ are linear functions both in the state and the control variable, that is in (y, u) , all the second derivatives of $h(\cdot, q)$ are equal to zero, then $\det(\mathbf{F})(y, u, q) = 0$, which implies that either a steady state does not exist, or there is an infinite number of steady states (and possibly a solution to the problem does not exist);
2. if h is linear in the control variable, that is if $h_{uu} = h_{yu} = h_{uy} = 0$ then $\det(\mathbf{F}) = -(g_u)^2 h_{yy}$, where g_u is a constant, and a steady state can exist, if $h_{yy} \neq 0$;
3. in several models applied to macroeconomics, the objective function is independent of the state variable, that is $f = f(u)$ which implies $h_{uy} = q g_{uy}$ and $h_{yy} = 0$. In this case, we have

$$\det(\mathbf{F}) = (g_y - \rho)(g_y h_{uu} - g_u q g_{uy}) - g_u g_y q g_{yu}$$

which does not rule out the existence of a steady state. However, if the constraint function is linear in u we cannot rule out that $\det(\mathbf{F}) = 0$. Indeed, this is the case in simple endogenous growth models and simple models for the representative household.

4. if functions $f(yu)$ and $g(y, u)$ are nonlinear, having locally $\det(\mathbf{F})(y, u, q) = 0$ provides a necessary condition for the existence of local bifurcations and of potentially complex dynamics in the solution of the optimal control problem. The number of cases is potentially enormous

and complex. In abstract we can say that any bounded trajectory converging to a steady state or a limit cycle is a candidate for optimality, although we cannot rule out the possibility of existence of multiple solutions.

If functions $f(\cdot)$ and $g(\cdot)$ are sufficiently smooth we may qualitative characterize the optimal dynamics of (y, q) (or for (y, u)).

The algebraic equation in system (8.29) allows us to determine uniquely the control variable. If $\partial^2 h / \partial u^2 \neq 0$, the implicit function theorem allows for obtaining from the optimality condition for u , $h_u(u, y, q) = 0$, an implicit representation of the control as a function of the state and co-state variables $u = U(y, q)$.

Assume that $h_{uu}(y, u, q) \neq 0$ for any $(y, u, q) \in Y \times U \times Q$. Then, from the implicit function theorem, we can find uniquely the control as a function of the state and the co-state variables

$$u = U(y, q)$$

where, from the implicit function theorem

$$U_y = -\frac{h_{uy}}{h_{uu}}, \text{ and } U_q = -\frac{g_u}{h_{uu}}.$$

If we substitute this control representation in the differential equations of (8.29) we obtain the **modified Hamiltonian dynamic system** (MHDS) as a non-linear planar ODE,

$$\begin{pmatrix} \dot{y} \\ \dot{q} \end{pmatrix} = \mathbf{M}(y, q) \equiv \begin{pmatrix} g(y, U(y, q)) \\ \rho q - h_y(y, U(y, q), q) \end{pmatrix}. \quad (8.30)$$

The Jacobian of the MHDS is

$$\begin{aligned} D\mathbf{M}(y, q) &= \begin{pmatrix} \frac{\partial \dot{y}(y, q)}{\partial y} & \frac{\partial \dot{y}(y, q)}{\partial q} \\ \frac{\partial \dot{q}(y, q)}{\partial y} & \frac{\partial \dot{q}(y, q)}{\partial q} \end{pmatrix} \\ &= \begin{pmatrix} g_y(y, q) + g_u(y, q) U_y(y, q) & g_u(y, q) U_q(y, q) \\ -h_{yy}(y, q) - h_{yu}(y, q) U_y(y, q) & \rho - h_{yu}(y, q) U_q(y, q) - h_{yq}(y, q) \end{pmatrix}. \end{aligned}$$

Lemma 1. *Let $\rho > 0$ and assume that $h_{uu}(y, u, q) \neq 0$ for any $(y, u, q) \in Y \times U \times Q$. Then the Jacobian $D\mathbf{M}(y, q)$ has trace $\text{trace } D\mathbf{M}(y, q) = \rho > 0$ for any point $(y, q) \in Y \times Q$.*

Proof. Has $g_u U_y = -g_u \frac{h_{uy}}{h_{uu}} = h_{uy} U_q = -h_{uy} \frac{g_u}{h_{uu}}$, we readily see that the Jacobian matrix has the following

$$D\mathbf{M}(y, q) = \begin{pmatrix} M_{11}(y, q) & M_{12}(y, q) \\ M_{21}(y, q) & \rho - M_{11}(y, q) \end{pmatrix}$$

Therefore $\text{trace } D\mathbf{M}(y, q) = M_{11} + \rho - M_{11} = \rho > 0$ □

Observe that this result has a global nature. The only requirement is that $h_{uu} \neq 0$ globally. This assures that there is steady state and that there are no singularities²

Assume the MHDS has, at least, one steady state, $(\bar{y}, \bar{q}) = \{(y, q) : \dot{y} = \dot{q} = 0\}$. In the neighbourhood of (\bar{y}, \bar{q}) we can approximate the non-linear MHDS (8.30) by the linear system

$$\begin{pmatrix} \dot{y}(t) \\ \dot{q}(t) \end{pmatrix} = D_{(y,q)} \mathbf{M}(\bar{y}, \bar{q}) \begin{pmatrix} y(t) - \bar{y} \\ q(t) - \bar{q} \end{pmatrix}$$

where the Jacobian, evaluated at the steady state (\bar{y}, \bar{q}) is the matrix of constants

$$D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q}) = \begin{pmatrix} \frac{\partial \dot{y}(\bar{y}, \bar{q})}{\partial \dot{q}(\bar{y}, \bar{q})} & \frac{\partial \dot{y}(\bar{y}, \bar{q})}{\partial q} \\ \frac{\partial \dot{q}(\bar{y}, \bar{q})}{\partial y} & \frac{\partial \dot{q}(\bar{y}, \bar{q})}{\partial q} \end{pmatrix}.$$

If functions $f(\cdot)$ and $g(\cdot)$ have no singularities we can obtain a generic characterization of the dynamics of the MHDS, and, therefore, of the solution to the optimal control problem.

Proposition 5. *Let there be a steady state (\bar{y}, \bar{q}) for the MHDS system. This steady state can never be locally a stable node or focus. There is transitional dynamics converging to the steady state only if it is a saddle point, that is if $\det(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) < 0$.*

Proof. Evaluating the Jacobian at a steady state (\bar{y}, \bar{q}) , with $\bar{u} = u(\bar{y}, \bar{q})$, we find that the Jacobian matrix becomes a matrix of constants

$$D_{(y,q)} \mathbf{M}(\bar{y}, \bar{q}) = \begin{pmatrix} \bar{g}_y - \frac{\bar{g}_u \bar{h}_{uy}}{\bar{h}_{uu}} & -\frac{(\bar{g}_u)^2}{\bar{h}_{uu}} \\ -\bar{h}_{yy} + \frac{(\bar{h}_{uy})^2}{\bar{h}_{uu}} & \rho - \bar{g}_y + \frac{\bar{g}_u \bar{h}_{uy}}{\bar{h}_{uu}} \end{pmatrix}$$

where $\bar{g}_y = g(u(\bar{y}, \bar{q}), \bar{y})$, etc³. Observe that the Jacobian matrix has a particular structure

$$D_{(y,q)} \mathbf{M}(\bar{y}, \bar{q}) = \begin{pmatrix} a & b \\ c & \rho - a \end{pmatrix}. \quad (8.31)$$

implying that the trace is equal to the rate of time preference,

$$\text{trace}(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) = \rho > 0 \quad (8.32)$$

and is always positive and

$$\det(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) = a(\rho - a) - bc. \quad (8.33)$$

This implies that, if there is a steady state, it can never be a stable node or focus. Therefore, it can be an unstable node or focus if $\det(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) > 0$, a saddle-point if $\det(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) < 0$ or a degenerate saddle node if $\det(D_{(q,y)} \mathbf{M}(\bar{y}, \bar{q})) = 0$. There can only be transitional dynamics if it is a saddle-point. \square

²In Brito et al. (2017) we deal with the case in which we can have locally $h_{uu} = 0$. This tends to make the solution to be non-unique locally for a subset of the space $Y \times Q$.

³because if $h(\cdot)$ is continuous then $h_{uy}(\cdot) = h_{yu}(\cdot)$.

Then we can conclude the following:

1. in generic cases the equilibrium point (\bar{y}, \bar{q}) is a saddle point if $\det(D_{(q,y)}\mathbf{M}(\bar{y}, \bar{q})) < 0$, and:
 - (a) the stable manifold associated with (\bar{y}, \bar{q})

$$W^s = \{ (y, q) \in Y \times Q \subseteq \mathbb{R}^2 : \lim_{t \rightarrow \infty} (y(t), q(t)) = (\bar{y}, \bar{q}) \}$$

passing through point $y(0) = y_0$ **is the solution set of the OC problem**;
 - (b) the solution to the OC problem is (at least locally) unique;
 - (c) the optimal trajectory is asymptotically tangent to the stable eigenspace E^s associated to Jacobian $D_{(q,y)}\mathbf{M}(\bar{y}, \bar{q})$
2. if $\det(D_{(q,y)}\mathbf{M}(\bar{y}, \bar{q})) > 0$ the equilibrium point is unstable. In this case the candidate solutions tend to diverge away from the steady state. The existence of a solution depends on the satisfaction of the transversality condition (equation (8.28b)). If this is the case, the solution to the optimal control problem is **non-stationary**, that is, it will be asymptotically unbounded;
3. if $\det(D_{(q,y)}\mathbf{M}(\bar{y}, \bar{q})) = 0$, there will be an infinite number of candidate steady states. The system is "anchored" however by the initial condition $y(0) = y_0$, which means that the solution to the optimal control problem exists, it is unique, but it is **stationary**;

A relatively common problem in economics, involve functions $f(y, u)$ and $g(y, u)$, in which g is a linear function and f is independent from the state variable, that is $f = f(u)$ with $f_{uu} < 0$ and $g(y, u) = ay + bu$. In this case, which is common in economics, the last two cases tend to occur:

1. the MHDS has the structure of matrix (8.31) with possibly the coefficients a , b and c linearly dependent upon y and/or q . In this case a steady state (unless at $y = u = 0$) and the MHDS displays unbounded growth. This means that evaluating the MHDS at the steady state the determinant (8.33) will be positive. The existence of a solution depends on the satisfaction of the transversality condition (equation (8.28b)). If this is the case, the solution to the optimal control problem is **non-stationary**, that is, it will be asymptotically unbounded;
2. the MHDS has the structure of matrix (8.31) with $a = \rho$ and $b = 0$. In this case, the $\det(D_{(q,y)}\mathbf{M}(\bar{y}, \bar{q})) = 0$ and there will be an infinite number of candidate steady states. The system is "anchored" however by the initial condition $y(0) = y_0$, which means that the solution to the optimal control problem exists, it is unique, but it is **stationary**;

Conclusion

Therefore, if there is a unique solution to the infinite-horizon discounted optimal control problem, and if the constitutive functions are monotonic, three types of solutions can occur:

1. a unique time varying solution converging to a steady state;
2. a stationary solution;
3. an time-varying unbounded solution which grows in time such that is satisfies the transversality condition.

A last message: be careful if your optimal control problem has linear constitutive functions.

8.5 Economic applications

We consider the same problems as in the calculus of variations section.

8.5.1 Two simple problems

Example 1: Resource depletion problem

The (non-renewable) resource depletion problem can now be solved by using the Pontryagin's principle. Recall that the problem is

$$\max_{c(\cdot)} \int_0^{\infty} e^{-\rho t} \ln(c(t)) dt, \quad \rho > 0$$

subject to

$$\begin{cases} \dot{w}(t) = -c(t), & t \in [0, \infty) \\ w(0) = w_0, & \text{given} \\ \lim_{t \rightarrow \infty} w(t) \geq 0. \end{cases}$$

In this problem, the control variable is consumption, C , and the state variable is the remaining level of the resource, W . What is the best path for consumption-depletion ?

For applying the Pontryagin maximum principle we write the current-value Hamiltonian

$$h = \ln(c) - q c.$$

The first order conditions are

$$\begin{aligned} c(t) &= 1/q(t) \\ \dot{q} &= \rho q(t) \\ \lim_{t \rightarrow \infty} e^{-\rho t} q(t) w(t) &= 0 \\ \dot{w} &= -c(t) \\ w(0) &= w_0 : \end{aligned}$$

and can be written as a planar differential equation in (w, c) , together with the initial and the transversality condition is

$$\begin{aligned}\dot{w} &= -c(t) \\ \dot{c} &= -\rho c(t) \\ w(0) &= w_0 \\ \lim_{t \rightarrow \infty} e^{-\rho t} \frac{w(t)}{c(t)} &= 0\end{aligned}$$

If we want to find the solution we must solve the system, together with the conditions on time.

There are several ways to solve it. Here is a simple one. First, define $z(t) \equiv w(t)/c(t)$. Time-differentiating and substituting, we get the scalar terminal-value problem

$$\begin{cases} \dot{z} = -1 + \rho z \\ \lim_{t \rightarrow \infty} e^{-\rho t} z(t) = 0 \end{cases}$$

which has a constant solution $z(t) = \frac{1}{\rho}$ for every $t \in [0, \infty)$. Second, substitute $c(t) = w(t)/z(t) = \rho w(t)$. therefore,

$$\begin{cases} \dot{w} = -c(t) = -\rho w(t) \\ w(0) = w_0 \end{cases}$$

Then $w^*(t) = w_0 e^{-\rho t}$ for $t \in [0, \infty)$ and $c^*(t) = \rho w^*(t)$.

Characterization of the solution: there is asymptotic extinction

$$\lim_{t \rightarrow \infty} w^*(t) = 0,$$

at a speed given by the half-life of the process

$$\tau \equiv \left\{ t : w^*(t) = \frac{w(0) - w^*(\infty)}{2} \right\} = -\frac{\ln(1/2)}{\rho}$$

if $\rho = 0.02$ then $\tau \approx 34.6574$ years.

Example 2: the consumption-savings problem

Problem: find the functions $(a(t), c(t))$ pair that maximizes the functional

$$\max_{c(\cdot)} \int_0^\infty e^{-\rho t} \frac{c(t)^{1-\theta} - 1}{1-\theta} dt, \quad \rho > 0$$

subject to

$$\begin{cases} \dot{a}(t) = y - c(t) + r a, \quad t \in [0, \infty) \\ a(0) = a_0, \text{ given} \\ \lim_{t \rightarrow \infty} a(t)^{-r t} \geq 0. \end{cases}$$

In this problem, the control variable is consumption, c , and the state variable is the level of net wealth, a . The current value Hamiltonian is

$$h(a, c, q) = \frac{c^{1-\theta} - 1}{1-\theta} + q(y - c + r a)$$

and the first order conditions according to the Pontryagin's principle are

$$\begin{cases} c(t)^{-\theta} = q(t) \\ \dot{q} = q(\rho - r) \\ \dot{a} = y - c + r a \\ a(0) = a_0 \\ \lim_{t \rightarrow \infty} q(t) a(t) e^{-\rho t} = 0 \end{cases}$$

As

$$\frac{\dot{q}}{q} = -\theta \frac{\dot{c}}{c}$$

we can obtain the solution by solving the mixed initial-terminal value problem for ODE's

$$\begin{cases} \dot{a} = y - c + r a \\ \dot{c} = \gamma c \\ a(0) = a_0 \\ \lim_{t \rightarrow \infty} c(t)^{-\theta} a(t) e^{-\rho t} = 0 \end{cases}$$

where again $\gamma \equiv \frac{r - \rho}{\theta}$. We present and discuss next the solution to this problem.

8.5.2 Qualitatively specified problems

Next we present a general Ramsey (1928) model in which the behavioral functions are qualitatively specified. This allows us to study the qualitative solution to the optimal control problem.

The Ramsey problem is:

$$\begin{aligned} & \max_{c(\cdot)} \int_0^\infty e^{-\rho t} U(c(t)) dt, \quad \rho > 0, \\ & \text{subject to} \\ & \dot{k}(t) = F(k(t)) - c(t), \quad t \in [0, \infty) \\ & k(0) = k_0 \text{ fixed} \\ & \lim_{t \rightarrow \infty} e^{-\rho t} k(t) \geq 0. \end{aligned}$$

We also assume that $(k, c) : \mathbb{R}_+ \rightarrow \mathbb{R}_+^2$. In this problem the control variable is c and the state variable is the stock of capital k .

The utility and the production functions, $u(c)$ and $F(k)$, are usually assumed to have the following properties: Increasing, concave and Inada :

$$U'(\cdot) > 0, U''(\cdot) < 0, F'(\cdot) > 0, F''(\cdot) < 0$$

$$U'(0) = \infty, U'(\infty) = 0, F'(0) = \infty, F'(\infty) = 0.$$

Although we do not have explicit utility and production functions we can still characterize the optimal consumption-accumulation process (we are using the Grobman-Hartmann theorem).

The current-value Hamiltonian is

$$h(c, k, q) = U(c) + q(F(k) - c)$$

The necessary (and sufficient) conditions according to Pontryagin's maximum principle are

$$\begin{aligned} U'(c(t)) &= q(t) \\ \dot{q} &= q(t) (\rho - F'(k(t))) \\ \lim_{t \rightarrow \infty} e^{-\rho t} q(t) k(t) &= 0 \\ \dot{k} &= F(k(t)) - c(t) \\ k(0) &= k_0 \end{aligned}$$

The MHDS and the initial and transversality conditions become

$$\begin{aligned} \dot{k} &= F(k(t)) - c(t) \\ \dot{c} &= \frac{c(t)}{\theta(c(t))} (F'(k(t)) - \rho) \\ k(0) &= k_0 > 0 \\ 0 &= \lim_{t \rightarrow \infty} e^{-\rho t} U'(c(t)) k(t) \end{aligned}$$

where $\theta(c) = -\frac{U''(c)c}{U'(c)} > 0$ is the inverse of the elasticity of intertemporal substitution.

The MHDS has no explicit solution (it is not even explicitly defined) : we can only use **qualitative methods**. They consist in:

- determining the steady state(s): (\bar{c}, \bar{k})
- characterizing the linearised dynamics (it is useful to build a phase diagram).

The steady state (if $k > 0$) is

$$\begin{aligned} F'(\bar{k}) &= \rho \Rightarrow \bar{k} = (F')^{-1}(\rho) \\ \bar{c} &= F(\bar{k}) \end{aligned}$$

The linearized MHDS is

$$\begin{pmatrix} \dot{k} \\ \dot{c} \end{pmatrix} = \begin{pmatrix} \rho & -1 \\ \frac{\bar{c}}{\theta(\bar{c})} F''(\bar{k}) & 0 \end{pmatrix} \begin{pmatrix} k(t) - \bar{k} \\ c(t) - \bar{c} \end{pmatrix}$$

where we denote $D\mathbf{M}$ the Jacobian matrix. The jacobian J has trace and determinant:

$$\text{tr}(D\mathbf{M}) = \rho, \quad \det(D\mathbf{M}) = \frac{\bar{c}}{\theta(\bar{c})} F''(\bar{k}) < 0$$

the steady state (\bar{c}, \bar{k}) is a saddle point. The eigenvalues of $D\mathbf{M}$ are

$$\lambda_s = \frac{\rho}{2} - \sqrt{\Delta} < 0, \quad \lambda_u = \frac{\rho}{2} + \sqrt{\Delta} > \rho > 0$$

where the discriminant is

$$\Delta = \left(\frac{\rho}{2}\right)^2 - \frac{\bar{c}}{\theta(\bar{c})} F''(\bar{k}) > \left(\frac{\rho}{2}\right)^2.$$

and the eigenvector matrix of $D\mathbf{M}$ is

$$\mathbf{P} = (\mathbf{P}^s \mathbf{P}^u) = \begin{pmatrix} 1 & 1 \\ \lambda_u & \lambda_s \end{pmatrix}$$

Then the approximate solution for the Ramsey problem, in the neighbourhood of the steady state, is

$$\begin{pmatrix} k^*(t) \\ c^*(t) \end{pmatrix} = \begin{pmatrix} \bar{k} \\ \bar{c} \end{pmatrix} + k_0 \begin{pmatrix} 1 \\ \lambda_u \end{pmatrix} e^{\lambda_s t}, \quad t \in [0, \infty) \quad (8.34)$$

Then the local stable manifold has slope higher than the isocline $\dot{k}(C, K) = 0$

$$\left. \frac{dc}{dk} \right|_{W^s} = \lambda_u > \left. \frac{dc}{dk} \right|_{\dot{k}} = F'(\bar{k}) = \rho$$

Geometrically (see figure 8.1) the **approximate** solution (8.34) belongs to the stable sub space E^s

$$E^s = \{ (k, c) : (c - \bar{c}) = \lambda_u (k - \bar{k}) \}$$

while the **exact** solution belongs to the stable manifold W^s (which cannot be determined explicitly). Observe that while the slope of the isocline in the neighborhood of the steady is flatter than the slope of the stable manifold

$$\left. \frac{dc}{dk} \right|_{k=0} = F'(\bar{k}) = \rho < \left. \frac{dc}{dk} \right|_{W^s} = \lambda_u$$

meaning that the solution approaches the steady state by accumulating (reducing) capital is the initial capital level is smaller (bigger) than the steady state level.

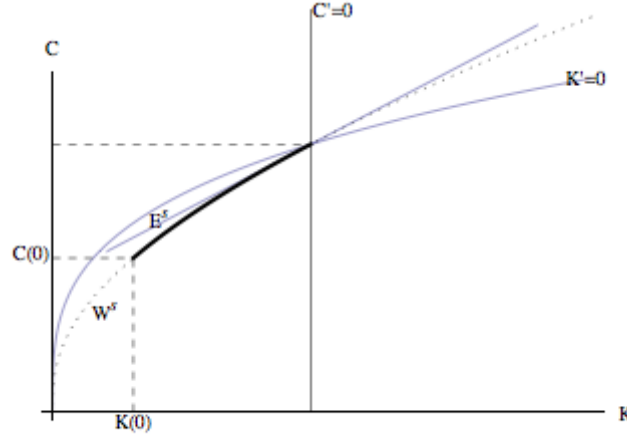

Figure 8.1: The phase diagram for the Ramsey model: it depicts the isoclines $\dot{c} = 0$ and $\dot{k} = 0$, the stable manifold W^s and the stable eigenspace, E^s , which is tangent asymptotically to the stable manifold. The exact solution follows along the stable manifold, but we have determined just the approximation along the stable eigenspace.

8.5.3 Unbounded solutions

In the previous section we saw that if the solution converges to a steady state we can have a qualitative characterization of the solution appealing to the Grobman-Hartman theorem. However, in some cases, in particular in endogenous growth theory models, solutions may not converge to a steady state, or the solution which interests us can be unbounded in time.

In particular, the consumer-saver problem may have an unbounded solution:

$$\begin{aligned} & \max_{c(\cdot)} \int_0^\infty e^{-\rho t} U(C(t)) dt, \quad \rho > 0, \\ & \text{subject to} \\ & \dot{A}(t) = Y - C + rA, \quad t \in [0, \infty) \\ & A(0) = A_0 \text{ fixed} \\ & \lim_{t \rightarrow \infty} e^{-\rho t} A(t) \geq 0. \end{aligned}$$

If we write the MHDS in the (A, Q) space, we have

$$\begin{cases} \dot{A} = Y - Q^{-\frac{1}{\theta}} + rA \\ \dot{Q} = Q(\rho - r) \end{cases}$$

the solution of the optimal control problem are the solutions of that MHDS together with the initial and transversality conditions

$$A(0) = a_0, \quad \lim_{t \rightarrow \infty} Q(t)A(t)e^{-\rho t} = 0.$$

There are two interesting cases. First, if $r = \rho$ then there is an infinity of stationary solutions satisfying $Q^{-\frac{1}{\theta}} = Y + rA$. Second, if $r \neq \rho$ it has no steady state in \mathbb{R} . To see this note that, $\dot{Q} = 0$ if and only if $Q = 0$ but then $\dot{A} = 0$ can only be reached asymptotically when $A \rightarrow \infty$.

We can have a clearer characterization if we recast the problem in the (A, C) spac. Recall that in this case we have the MHDS

$$\begin{cases} \dot{A} = Y - C + rA \\ \dot{C} = \gamma C, \end{cases}$$

where

$$\gamma \equiv \frac{r - \rho}{\theta},$$

which, for the moment, we assume has an ambiguous sign.

The solution of the optimal control problem are the solutions of that MHDS together with the initial and transversality conditions

$$\begin{cases} A(0) = a_0, \\ \lim_{t \rightarrow \infty} c(t)^{-\frac{1}{\theta}} A(t) e^{-\rho t} = 0. \end{cases}$$

The MHDS is linear planar ODE with coefficient matrix is

$$\mathbf{A} = \begin{pmatrix} r & -1 \\ 0 & \gamma \end{pmatrix}$$

that has eigenvalues

$$\lambda_- = \gamma, \lambda_+ = r > 0.$$

and has eigenvector matrix

$$\mathbf{P} = \begin{pmatrix} 1 & 1 \\ r - \gamma & 0 \end{pmatrix}$$

The solution to the MHDS is, for $\gamma \neq 0$

$$\begin{pmatrix} A(t) \\ c(t) \end{pmatrix} = \begin{pmatrix} -\frac{Y}{r} \\ 0 \end{pmatrix} + h_- \begin{pmatrix} 1 \\ r - \gamma \end{pmatrix} e^{\gamma t} + h_+ \begin{pmatrix} 1 \\ 0 \end{pmatrix} e^{rt}.$$

For later use, observe that the trajectories starting from $A(0) = a_0$ and travelling along the eigenspace associated to eigenvalue λ_- are

$$\begin{pmatrix} A(t) \\ c(t) \end{pmatrix} = \begin{pmatrix} -\frac{Y}{r} \\ 0 \end{pmatrix} + (A_0 + \frac{Y}{r}) \begin{pmatrix} 1 \\ r - \gamma \end{pmatrix} e^{\gamma t}.$$

that is

$$\mathbb{E}^- = \left\{ (A, C) \in \mathbb{R} \times \mathbb{R}_+ : C = (r - \gamma) \left(A + \frac{Y}{r} \right) \right\}.$$

We saw that the only requirement for the transversality condition to be met, and therefore for the optimal control problem to have a solution was $r > \gamma$. Even if we keep this assumption, three cases are possible

1. if $r < \rho$ then $\lambda_- = \gamma < 0$ and the steady state $(\bar{A}, \bar{C}) = (-Y/r, 0)$ is a saddle-point. The solution of the optimal control problem, which lies along the stable manifold converges to $c^*(\infty) = 0$ and $A^*(\infty) = -Y/r < 0$. The steady state is a saddle point. The intuition is: the consumer is more impatient than the market and therefore will be asymptotically a debtor to a point in which it can collateralize the debt by its human capital $A(\infty) + H(0) = 0$;
2. if $\gamma < r = \rho$ then $\lambda_- = 0$ and the solution is constant $c^*(t) = Y + rA_0$ and $A^*(t) = A_0$ for all $t \in [0, \infty)$. This was the case corresponding to the existence of an infinite number of equilibria when the characterization is conducted in the (A, Q) space;
3. if $r > \rho$ then $\lambda_- = \gamma > 0$ and the steady state $(\bar{A}, \bar{C}) = (-Y/r, 0)$ is an unstable node. In this case, there are admissible solutions only if $A_0 \geq -Y/r$, otherwise consumption would be negative. However, if $A_0 > -Y/r$ there is an admissible solution to the optimal control problem but it is unbounded.

The question the last case poses is the following. First, if we look at the MHDS as a dynamical system we would say that it is unstable but most of the qualitative theory of ODE characterizes the dynamics close to a steady state. But we already found that this case is indeed a solution to the optimal control problem. How can we reconcile the two points ?

A way to deal with the last type of behavior is to consider convergence of the solution to a kind of invariant structure and to consider convergence to that structure. An approach which is used in the economic growth literature (see Acemoglu (2009)) is to consider convergence to an exponential solution, called **balanced growth path**, such that the initial and the transversality conditions hold.

The method proceeds along five steps.

First, define the variables using multiplicative deviations along an exponential trends with proportional growth rates. In our case we try the case in which the rates of growth are equal

$$A(t) = a(t)e^{gt}, \quad c(t) = c(t)e^{gt}$$

Second, obtain the dynamic system for the detrended variables (a, c) . If we observe that

$$\frac{\dot{a}}{a} = \frac{\dot{A}}{A} - g, \quad \frac{\dot{c}}{c} = \frac{\dot{C}}{C} - g,$$

we get

$$\begin{cases} \dot{a} = Ye^{-gt} - c + (r - g)a \\ \dot{c} = (\gamma - g)c \end{cases}$$

Third, obtain g from a stationary solution to the system in detrended variables. In our case setting $g = \gamma$ transforms the previous system to

$$\begin{cases} \dot{a} = Ye^{-\gamma t} - c + (r - \gamma)a \\ \dot{c} = 0 \end{cases}$$

which implies that $c(t) = \bar{c}$ which is an unknown constant. Setting $a(0) = A_0$ and $c(t) = \bar{c}$ we can solve the equation for the detrended asset holdings

$$a(t) = \left(A_0 - \frac{\bar{c}}{r - \gamma} + \frac{Y}{r} (1 - e^{-rt}) \right) e^{(r - \gamma)t} + \frac{\bar{c}}{r - \gamma}.$$

Fourth, we can determine \bar{c} from the transversality condition

$$\begin{aligned} \lim_{t \rightarrow \infty} (c(t))^{-\theta} A(t) e^{-\rho t} &= \lim_{t \rightarrow \infty} \bar{c}^{-\theta} e^{(\gamma(1-\theta) - \rho)t} a(t) = \\ &= \lim_{t \rightarrow \infty} \bar{c}^{-\theta} e^{(\gamma(\theta-1) - \rho + r - \gamma)t} \left(A_0 - \frac{\bar{c}}{r - \gamma} + \frac{Y}{r} (1 - e^{-rt}) + \frac{\bar{c}}{r - \gamma} e^{-(r - \gamma)t} \right) = \\ &= \lim_{t \rightarrow \infty} \bar{c}^{-\theta} \left(A_0 - \frac{\bar{c}}{r - \gamma} + \frac{Y}{r} (1 - e^{-rt}) + \frac{\bar{c}}{r - \gamma} e^{-(r - \gamma)t} \right) = \\ &= \bar{c}^{-\theta} \left(A_0 - \frac{\bar{c}}{r - \gamma} + \frac{Y}{r} \right) = 0 \end{aligned}$$

if and only if $\bar{c} = c^* = (r - \gamma) \left(A_0 + \frac{Y}{r} \right)$.

At last we get the solution

$$c^*(t) = c^* e^{\gamma t}, \quad A^*(t) = a^*(t) e^{\gamma t}$$

where

$$c^* = (r - \gamma) \left(a_0 + \frac{Y}{r} \right), \quad a^*(t) = A_0 + \frac{Y}{r} (1 - e^{-\gamma t}).$$

We see that

$$c^*(t) = (r - \gamma) \left(A^*(t) + \frac{Y}{r} \right), \text{ for } t \in [0, \infty)$$

which means that the solution to the optimal control problem evolves along the eigenspace associated to the eigenvalue λ_- (see figure 8.2).

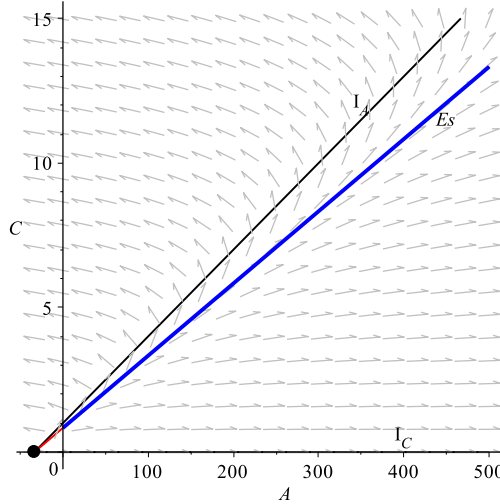

Figure 8.2: Phase diagram for the benchmark consumer problem for the case $r > \gamma$.

If $r < \rho$, and therefore $\gamma < 0$, the solution evolves along the eigenspace associated to λ_- but it converges to the steady state in which $A(\infty) = -Y/r$. In this case $\mathbb{E}^- = \mathbb{E}^s$ that is this is the stable eigenspace (which as the model is linear is the stable manifold).

From this we have a geometrical interpretation of the solution to the optimal control problem: if $r \neq \rho$ the solution will belong to the eigenspace \mathbb{E}^- , and it converges to the steady state if $r < \rho$ and diverges from it if $r > \rho$.

This illustrates, and reinforces, the fact that interpreting phase diagrams for MHDS of optimal control problems should be done with care: if the optimal control problem has a single solution, the geometrical analog of it is also unique.

Chapter 9

Introduction to the dynamic programming approach

The dynamic programming principle provides another approach to solve optimal control problems. It is based upon the principle of dynamic programming that states basically that finding an optimal solution to the problem may be achieved by finding the best rule for the immediate (infinitesimal in continuous time) step. In the literature it is associated to a recursive approach to solving the problem or to finding a feedback rule.

The first order conditions according to the principle of dynamic programming are represented by the Hamilton-Jacobi-Bellman (HJB) equation which is a partial differential equation (for the finite horizon problem) or a implicit ordinary differential equation (for the infinite horizon problem).

It has some advantages and some disadvantages when compared to the maximum principle approach:

- on the plus side: it provides a clearer intuition to dynamic optimization, it allows for an easier extension to stochastic optimal control problems, and, it is preferred by researchers who prefer to solve problems numerically;
- on the minus side: giving place to a differential equation, the terminal condition to solving that equation is not always clear (in fact it is a way to circumvent the need to a terminal condition; studying the differentiability properties of the HJB equation requires advanced functional analysis; and does not lead immediately to the use of the qualitative theory of ODE's to qualitative analysing of the solution. However, we will see that this shortcoming can be eliminated by the use of the envelope theorem.

9.1 The finite horizon case

Consider again the free terminal state optimal control problem: among functions $y \in Y$ and $u \in U$ satisfying

$$\dot{y} = G(y(t), u(t), t), \text{ for } t \in [0, \bar{t}] \quad (9.1)$$

and $y(0) = y_0$ find the pair (y^*, u^*) that maximize the functional

$$J[y, u] \equiv \int_0^{\bar{t}} F(t, y(t), u(t)) dt \quad (9.2)$$

where \bar{t} is given and $y^*(\bar{t})$ is free.

Proposition 1 (Necessary conditions according to the principle of dynamic programming). *Consider the optimal state and control functions $y^* \in Y$ and $u^* \in U$ for the optimal control problem with free terminal state. Then the **Hamilton-Jacobi-Bellman** equation must hold*

$$-V_t(t, y) = \max_{u \in U} \{ F(t, y, u) + V_y(t, y)G(t, y, u) \} \quad (9.3)$$

for all $t \in [0, \bar{t})$ and all $y \in Y \subseteq \mathbb{R}$.

Proof. (heuristic) We define the functional over the state and control functions continuing from an arbitrary time $t \geq 0$: $(y, u) : [t, \bar{t}] \rightarrow Y \times U \subseteq \mathbb{R}^2$

$$J[y, u](t) = \int_t^{\bar{t}} F(s, y(s), u(s)) ds.$$

and call **value function** to

$$V(t, y(t)) \equiv \max_{(u(s)|s \in [t, \bar{t}])} J[y, u; t]$$

for $y(t) \in Y$.

The **Principle of dynamic programming optimality** states the following: for every $(t, y) \in [0, \bar{t}] \times Y$ and every $\Delta t \in (0, \bar{t} - t]$ the value function satisfies

$$V(t, y(t)) = \max_{(u(s)|s \in [t, t+\Delta t])} \left\{ \int_t^{t+\Delta t} F(s, y(s), u(s)) ds + V(t + \Delta t, y(t + \Delta t)) \right\}$$

where

$$y(t + \Delta t) = y(t) + G(t, y(t), u(t))\Delta t + o(\Delta t).$$

Performing a first-order Taylor expansion we get

$$V(t + \Delta t, y(t + \Delta t)) = V(t, y(t)) + V_t(t, y(t))\Delta t + V_y(t, y(t))G(t, y(t), u(t))\Delta t + o(\Delta t)$$

(this requires that V is C^1). If the interval Δt is sufficiently small we can use the mean-value theorem

$$\int_t^{t+\Delta t} F(s, y(s), u(s)) ds = F(t, y(t), u(t))\Delta t$$

Then

$$V(t, y(t)) = \max_{(u(s)|s \in [t, t+\Delta t])} \left\{ F(t, y(t), u(t))\Delta t + V(t, y(t)) + V_t(t, y(t))\Delta t + V_y(t, y)g(t, y(t), u(t))\Delta t + o(\Delta t) \right\}.$$

Cancelling out $V(t, y(t))$, dividing by Δt , taking $\Delta t \rightarrow 0$ and observing that the pair $(t, y(t))$ is an arbitrary element of $T \times Y$ we get the HJB equation (9.3). \square

For solving the optimal control problem, while the Pontryagin's principle provides necessary conditions in a form of a initial-terminal value problem for a planar ODE, the principle of the dynamic programming provides a formula for evaluating the value of our resource in a recursive way and independent of time.

The HJB equation (9.3) is a PDE (partial differential equation).

9.2 Infinite horizon discounted optimal control problem

The infinite horizon discounted optimal control problem is, again, to find functions $u^* \in U$ and $y^* \in Y$ satisfying

$$\begin{cases} \dot{y} = g(y(t), u(t)), & t \in [0, \infty) \\ y(0) = y_0, \\ \lim_{t \rightarrow \infty} h(t)y(t) \geq 0 \end{cases}$$

that maximize the objective functional

$$J[y, u] \equiv \int_0^\infty e^{-\rho t} f(y(t), u(t)) dt$$

Proposition 2 (Necessary conditions according to the principle of dynamic programming for the infinite horizon problem). *Let (y^*, u^*) be the solution to the discounted infinite horizon problem. Then it satisfies the HJB equation*

$$\rho v(y) = \max_u \{ f(y, u) + v'(y)g(y, u) \} \quad (9.4)$$

Proof. For $y(t) = y$ the value function is

$$V(t, y) \equiv \int_t^\infty e^{-\rho s} f(y^*(s), u^*(s)) ds$$

Multiplying by a inverse of the discount factor, the value function becomes independent of the initial time,

$$e^{\rho t} V(t, y) = \int_t^\infty e^{-\rho(s-t)} f(y^*(s), u^*(s)) ds = v(y).$$

If we take derivatives of $V(t, y) = e^{-\rho t} v(y)$, we have $V_t(t, y) = -\rho e^{-\rho t} v(y)$ and $V_y(t, y) = e^{-\rho t} v'(y)$, which after substituting in equation (9.3) yields equation (9.4). \square

In the case of the discounted infinite horizon the HJB equation is not a PDE but an ODE in implicit form. In order to see this we need to determine another important element of the DP approach: the policy function.

If we define the function $h(u, y) \equiv f(y, u) + v'(y)g(y, u)$ the HJB equation (9.4) can be written as

$$\rho v(y) = \max_u h(u, y).$$

We can obtain the optimal control from the first-order condition

$$\frac{\partial h(u, y)}{\partial u} = 0.$$

If function $h(u, y)$ is monotonic as regards u , by appealing to the implicit function theorem, we can obtain the optimal control as a function of the state variable, $u^* = \pi(y)$. Function $\pi(\cdot)$ in the DP literature is called **policy function**. It gives the optimal control as a function of the state variable. This is why it is called a **feedback control** problem.

The reason for this is the following. If we substitute the policy function in equation (9.4) we finally obtain the HJB equation as an ODE in implicit form

$$\rho v(y) = f(\pi(y), y) + v'(y)g(\pi(y), y)$$

where the state variable y is the independent variable and the value function, $v(y)$, is the unknown function.

If we are able to determine a solution to this equation, we can usually specify the utility function, which means that we are able to obtain the optimal control as a function of the state variable. We can obtain the solution to the optimal control problem by substituting in the ODE constraint to get

$$\dot{y} = g(y, \pi(y)), \quad t \in [0, \infty)$$

which, together with the initial condition $y(0) = y_0$, would, hopefully, allow for the determination of the solution for the state variable.

If we can find the policy function, then obtaining the optimal dynamics for y reduces to solving an initial-value problem instead of a mixed initial-terminal value problem (or two-point boundary value problem) as is the case when we use the calculus of variations of the Pontryagin's principle approaches.

However, only in a very small number of cases we can obtain closed form solutions to the HJB equation. Next we show some cases in which this is possible.

9.3 Applications

9.3.1 Example 1: The resource depletion problem

We solve again resource-depletion problem for an infinite horizon

$$\max_C \int_0^\infty e^{-\rho t} \ln(C(t)) dt, \text{ s.t } \dot{W} = -C, W(0) = W_0$$

by using the DP principle.

The HJB equation is

$$\rho v(W) = \max_C [\ln(C) + v'(W)(-C)]$$

Policy function

$$\frac{1}{C^*} - v'(W) = 0 \Leftrightarrow C^* = (v'(W))^{-1}$$

Then the HJB becomes

$$\rho v(W) = -\ln(v'(W)) - 1$$

The textbook method for solving the HJB equation through is by using the **method of undetermined coefficients** after we make a conjecture over the form of the value function (no constructive way here).

Assume the trial function

$$v(W) = a + b \ln(W)$$

As $v'(W) = b/W$ and substituting and collecting terms we get

$$\rho a + 1 + \ln(b) = \ln(W) (1 - \rho b)$$

then $b = 1/\rho$ and $a = (\ln \rho - 1)/\rho$.

Then:

$$v(W) = \frac{\ln \rho - 1 + \ln(W)}{\rho}, \quad C^* = (v'(W))^{-1} = \rho W$$

A second method: the HJB equation is an ODE, where W is the independent variable, so we can try to solve it (this is a constructive method).

The HJB is equivalent to

$$v'(W) = e^{-(1+\rho v(W))}$$

ODE $y'(x) = e^{(a+by(x))}$ has the closed form solution

$$y(x) = \frac{1}{b} \left(-a + \ln \left(-\frac{1}{b(k+x)} \right) \right)$$

where k is an arbitrary constant. Then we determine

$$v(W) = -\frac{1}{\rho} \left(1 + \ln \left(\frac{1}{\rho(W+k)} \right) \right)$$

and

$$C^* = (V'(W))^{-1} = \rho(W+k)$$

Substituting in the constraint $\dot{W} = -C = -\rho(W + k)$, we get the solution

$$W(t) = -k + (W(0) + k)e^{-\rho t}.$$

The problem is somewhat incompletely specified, which reveals a potential problem when using the DP approach.

In our case, as it is natural to assume that $\lim_{t \rightarrow \infty} W(t) = 0$ we would obtain $k = 0$ and therefore we would get the same solution as from using the CV and Pontryagin's approaches:

$$C^*(t) = \rho W_0 e^{-\rho t}, \quad W^*(t) = W_0 e^{-\rho t}, \quad \text{for } t \in [0, \infty).$$

9.3.2 Example 2: The benchmark consumption-savings problem

Applying the HJB equation (9.4) to our problem we have

$$\rho v(A) = \max_C \left\{ \frac{C^{1-\theta} - 1}{1-\theta} + v'(A)(Y - C + rA) \right\}. \quad (9.5)$$

Define a indirect utility function by

$$\tilde{u}(v'(A)) = \max_C \left\{ \frac{C^{1-\theta} - 1}{1-\theta} - v'(A) C \right\}$$

and total wealth, summing up human and financial wealth, by $W(A) \equiv \frac{Y}{r} + A$, then the HJB equation (9.5) at the optimum is a implicit ODE

$$\rho v(A) = \tilde{u}(v'(A)) + r v'(A) W(A). \quad (9.6)$$

Solving the static utility problem we get the optimum policy for consumption

$$C^* = \pi(A) \equiv (v'(A))^{-\frac{1}{\theta}}.$$

as a function of the (unknown) marginal value function, and upon substitution yields

$$\tilde{u}(v'(A)) = \frac{1}{1-\theta} \left((v'(A))^{\frac{\theta-1}{\theta}} - 1 \right).$$

Therefore, equation (9.6) becomes

$$\rho v(A) = \frac{\theta}{1-\theta} (v'(A))^{\frac{\theta-1}{\theta}} - \frac{1}{1-\theta} + r v'(A) W(A) \quad (9.7)$$

To solve this (implicit ODE) equation, we use again the method of undetermined coefficients. Conjecturing the trial function

$$v(A) = a + b W(A)^{1-\theta},$$

with arbitrary parameters a and b . Then

$$v'(A) = b(1-\theta) W(A)^{-\theta}$$

and after substitution in equation (9.7) we get

$$a\rho + \frac{1}{1-\theta} = W(A)^{1-\theta} b\theta \left[\left(b(1-\theta) \right)^{-1/\theta} - (r-\gamma) \right]$$

where we have again $\gamma \equiv (r-\rho)/\sigma$. Setting both sides to zero, yields

$$a = \frac{1}{\rho(\theta-1)} \text{ and } b = \frac{(r-\gamma)^{-\theta}}{1-\theta}$$

Then, the value function is

$$v(A) = \frac{1}{1-\theta} \left[(r-\gamma)^{-\theta} \left(\frac{Y}{r} + A \right)^{1-\theta} - \frac{1}{\rho} \right].$$

Taking the derivative as regards A and substituting in the policy function for C , we find the optimal consumption in feedback form

$$C^*(A) = (r-\gamma) \left(\frac{Y}{r} + A \right)$$

which only makes sense if $r > \gamma$.

We can get the optimal asset path by substituting optimal consumption in the budget constraint

$$\dot{A}^* = Y + rA - C^*(A) = \gamma \left(\frac{Y}{r} + A \right).$$

Solving this equation with $A(0) = A_0$ we get the optimal paths for asset holdings

$$A^*(t) = -\frac{Y}{r} + \left(\frac{Y}{r} + A_0 \right) e^{\gamma t}, \text{ for } t \in [0, \infty),$$

and consumption

$$C^*(t) = (r-\gamma) \left(\frac{Y}{r} + A_0 \right) e^{\gamma t}, \text{ for } t \in [0, \infty).$$

Exercise Prove, by setting $\theta = 1$, that the value function for $u(C) = \ln(C)$ is

$$V(A) = \frac{1}{\rho} \left[\frac{r-\rho}{\rho} + \ln(\rho W(A)) \right].$$

Hint: use the property $f(x) = \exp(\ln f(x))$ and use the l'Hôpital theorem.

The utility function is a generalized logarithm $u(C) = \ln_\theta(C) = \frac{C^{1-\theta} - 1}{1-\theta}$. Sometimes in the literature people write

$$u(C) = \begin{cases} \frac{C^{1-\theta}}{1-\theta} & \text{if } \theta \neq 1 \\ \ln(C) & \text{if } \theta = 1 \end{cases}$$

The problem with this formulation is that if we cannot obtain the value function for the logarithm utility by setting the limit of $\theta = 1$ for the general case $\theta = 1$, which is

$$v(A) = \frac{(r-\gamma)^{-\theta}}{1-\theta} W(A)^{1-\theta}.$$

9.3.3 Example 3: The Ramsey model

The HJB for the Ramsey model is

$$\rho v(k) = \max_c \left\{ u(c) + v'(k) (F(k) - c) \right\}$$

The optimality condition is

$$u'(c) = v'(k)$$

if u is sufficiently smooth then we obtain the policy function $c = C(k) = (u')^{-1}(v'(k))$. Substituting back in the HJB equation yields the implicit ODE in $v(k)$

$$\rho v(k) = u(C(k)) + v'(k)(F(k) - C(k))$$

which does not have a closed form solution in general.

Exercise: for the case in which $u(c) = \frac{c^{1-\theta} - 1}{1-\theta}$ and $F(k) = k^\alpha$, such that $\theta = \alpha$ prove that a closed form solution can be found.

9.3.4 Example 4: The AK model

The Rebelo (1991) AK model can be seen as a special case of the previous problem in which the HJB function is

$$\rho v(K) = \max_C \left\{ \frac{C^{1-\theta}}{1-\theta} + v'(K) (AK - C) \right\}$$

Using the same steps as before, we get

$$\rho v(K) = \frac{\theta}{1-\theta} \left(v'(K) \right)^{\frac{\theta-1}{\theta}} + v'(K) AK \quad (9.8)$$

To solve the equation we use again the method of undetermined coefficients and find

$$v(K) = \frac{((A - \gamma)K)^{1-\theta}}{1-\theta}.$$

where

$$\gamma = \frac{A - \rho}{\theta}.$$

The consumption, in the feedback form is,

$$C^*(K) = (A - \gamma)K$$

and the budget constraint of the economy is

$$\dot{K}^* = AK^* - C^*(K) = \gamma K^*.$$

Considering the given initial level for capital $K(0) = K_0$ we get the optimal paths for capital and output

$$K^*(t) = K_0 e^{\gamma t}, \quad Y^*(t) = AK_0 e^{\gamma t}, \quad \text{for } t \in [0, \infty).$$

9.4 Relationship with the PMP

Consider the HJB equation (9.4).

The optimal policy function $u^* = U(y)$ is obtained from the optimality condition

$$f_u(y, u^*) + v'(y) g_u(y, u^*) = 0$$

Write $q = v'(y)$. Next we will show that with this change of variables we will obtain the optimality conditions according to the Pontryagin's maximum principle.¹

First, observe that, defining $h(y, u) = f(y, u) + v'(y) g(y, u) = f(y, u) + q g(y, u)$ at the optimum we have $h_u(y, u^*) = f_u(y, u^*) + q g_u(y, u^*) = 0$ is the static optimality condition according to the Pontryagin's maximum principle.

Taking the derivative of the (9.4), at the optimum, yields

$$\begin{aligned} \rho v'(y) &= f_y(y, u^*) + f_u(y, u^*) U'(y) + v''(y) g(y, u^*) + v'(y) (g_y(y, u^*) + g_u(y, u^*) U'(y)) \\ &= f_y(y, u^*) + v''(y) g(y, u^*) + v'(y) g_y(y, u^*) \end{aligned}$$

using the optimality condition. Therefore, if function $v(\cdot)$ is smooth

$$g(y, u^*) = \frac{\rho v'(y) - f_y(y, u^*) - v'(y) g_y(y, u^*)}{v''(y)} = \frac{\rho q - h_y(y, u^*)}{v''(y)} \quad (9.9)$$

using the previous definition. The constraint to the problem evaluated at the optimum, $\frac{dy}{dt} = g(y, u^*)$. Taking the time derivative of $q = v'(y)$ implies

$$\frac{dq}{dt} = v''(y) \frac{dy}{dt} = v''(y) g(y, u^*) =$$

If we substitute equation (9.9) yields

$$\frac{dq}{dt} = \rho q - h_y(y, u^*)$$

which is the multiplier equation from the Pontryagin's maximum principle²

This allows for a qualitative dynamics analysis of the solution to the optimal control problem obtained via the HJB equation.

9.4.1 Application to the Ramsey model

Consider the Ramsey problem with a CRRA utility function and a Cobb-Douglas production function. The HJB equation is

$$\rho v(k) = \max_c \left\{ \frac{c^{1-\theta} - 1}{1-\theta} + v'(k) (k^\alpha - c) \right\}$$

¹Although the DP approach is silent to what to do with the transversality condition. However, Ekeland (2010) shows that the solution to the problem exists if there is a steady state value for the state variable and at the steady state \bar{y} we should have $\rho v(\bar{y}) = v'(\bar{y})$.

²See (Beckmann, 1968, p.33).

where $\theta > 0$ and $0 < \alpha < 1$. The policy function is $c^* = C(k) = (v'(k))^{-\frac{1}{\theta}}$. Then

$$\frac{dc}{dt} = -\frac{c^* v''(k)}{\theta v'(k)} \frac{dk}{dt}.$$

From the envelop theorem, we obtain

$$\rho v'(k) = v''(k) (k^\alpha - c^*) + \alpha k^{\alpha-1} v'(k)$$

as

$$\frac{dk}{dt} = k^\alpha - c^* = \frac{v'(k) (\rho - \alpha k^{\alpha-1})}{v''(k)}$$

then

$$\frac{dc}{dt} = c \frac{(\alpha k^{\alpha-1} - \rho)}{\theta}$$

which is the Ramsey-Keynes equation associated to the PMP.

Chapter 10

Optimal control of ODE's: extensions

10.1 Introduction

In this chapter we consider some extensions of the simple optimal control problems we dealt in the last chapter

10.2 Singular optimal control

Assume that the Hamiltonian is linear in the control variable. This is equivalent to stating that $H_u(y, u, t) = h(y, t)$ and $H_{uu}(y, u) = 0$ for all $u \in \mathcal{U}$.

Consider the problem:

$$\begin{aligned} \max_{u(\cdot)} J[y, u] &= \int_0^T F(t, y(t), u(t)) dt \\ \text{subject to} & \\ \dot{y} &= G(t, y(t), u(t)) \\ y(0) &= y_0 \text{ given} \\ R(y(T), T) &\geq 0. \end{aligned} \tag{10.1}$$

In this case define the Hamiltonian function as

$$H(y, u, \lambda_0, \lambda, t) = \lambda_0 F(y, u, t) + \lambda G(y, u, t).$$

An informal version of the Pontryagin's principle states the following: If (y^*, u^*) is an optimum, then there is a scalar $\lambda_0 \in \{0, 1\}$ and a piecewise continuous function $\lambda : \mathbb{T} \rightarrow \mathbb{R}$ such that:

1. for every $t \in [0, T)$

$$\begin{aligned} H_u^*(t) &= 0 \\ \dot{\lambda} &= -H_y^*(t) \\ \dot{y} &= H_\lambda^*(t) = G(t, y^*(t), u^*(t)) \end{aligned}$$

2. at the terminal time $t = T$

$$\lambda(T) R_y^*(y(T), T) = 0$$

This problem may require enlarging the domain space, also for the state variable y to the set of piecewise-continuous functions $y : T \rightarrow \mathbb{R}$.

Here we are mostly concerned with the household problem with a linear utility function, that is a isoelastic utility function with an infinitely-valued elasticity of substitution. See (Grass et al., 2008, ch. 3.5) for a complete reference.

Example The household problem with a linear utility function

$$\begin{aligned} \max_{c(\cdot)} \quad & \int_0^\infty c(t) e^{-\rho t} dt \\ \text{subject to} \quad & \\ & \dot{a} = r a - c \\ & a(0) = a_0, \text{ fixed} \\ & \lim_{t \rightarrow \infty} e^{-r t} a(t) \geq 0 \end{aligned}$$

The Hamiltonian function is

$$H(a, c, \lambda_0, \lambda) = \lambda_0 c + \lambda (r a - c)$$

where λ_0 is a number and λ is a function of time. The first order conditions (observe that the Hamiltonian function is a concave, although not strictly concave function of (c, a)) are

$$\begin{aligned} \lambda_0 &= \lambda(t), \quad t \in T \\ \dot{\lambda} &= \lambda (\rho - r), \quad t \in T \\ \lim_{t \rightarrow \infty} \lambda(t) a(t) e^{-\rho t} &= 0 \\ \dot{a} &= r a - c \\ a(0) &= a_0. \end{aligned}$$

Setting $\lambda_0 = 1$ then $\lambda(t) = 1$ for every $t \in [0, \infty)$, which implies $\dot{\lambda} = 0$. A solution only exists if $r = \rho$, which we assume to be the case from now on. Solving the budget constraint and substituting in the transversality condition we should have $a_0 = \int_0^\infty e^{-\rho s} c(s) ds$. As there are no more constraints on the functional form for $c(t)$, as in the case with constant elasticity of substitution, the solution for c is indeterminate. That is, there is an infinite number of consumption trajectories that satisfies that constraint. In particular, a constant consumption path $c(t) = c^* = \rho a_0$ is a solution.

Setting $\lambda_0 = 0$ then $\lambda(t) = 0$ for every $t \in [0, \infty)$, which implies $\dot{\lambda} = 0$. However, this does not require that an existence condition is $r = \rho$. However, even if we assume that $r - \rho$ can have any sign, the transversality condition will be satisfied for any trajectories of a and c . Again, the solution is indeterminate.

From the economic point of view the problem is misspecified. In order to overcome this, either we introduce more curvature in the utility function, or we introduce some adjustment costs in consumption, or bounds in the net asset position of the consumer.

10.3 Two-stage optimal control problems

Assume that the independent variable is time $t \in T = [t_0, t_2]$ but there is a discontinuity in the objective function and/or in the constraint to the problem such that

$$F(t) = F(t, y(t), u(t)) = \begin{cases} F_1(t, y(t), u(t)) & \text{if } t_0 \leq t < t_1 \\ F_2(t, y(t), u(t)) & \text{if } t_1 \leq t \leq t_2 \end{cases}$$

and/or

$$G(t) = G(t, y(t), u(t)) = \begin{cases} G_1(t, y(t), u(t)) & \text{if } t_0 \leq t < t_1 \\ G_2(t, y(t), u(t)) & \text{if } t_1 \leq t \leq t_2 \end{cases}$$

where the *switching time* $t_1 \in T = [t_0, t_2]$, that is, it satisfies $t_0 < t_1 < t_2$, and may be known or may be a decision variable. The optimal control problem in which the switching time is a decision variable is called in the literature a **two-phase optimal control problem**.

The common structure of the problems we address in this section is

$$\max_{u(\cdot)} J[u, y] = \int_{t_0}^{t_1} F_1(t, y(t), u(t)) dt + \int_{t_1}^{t_2} F_2(t, y(t), u(t)) dt$$

subject to

$$\dot{y} = \begin{cases} F_1(t, y(t), u(t)) & \text{if } t_0 \leq t < t_1 \\ F_2(t, y(t), u(t)) & \text{if } t_1 \leq t \leq t_2 \end{cases} \quad (\text{PTS})$$

t_0 , and t_2 fixed

$y(t_0) = y_0$ fixed

$y(t_2) \geq y_2$ constrained

We consider the following versions of the problem depending on the switching conditions:

$$t_1 \text{ fixed and } y(t_1) \text{ free} \quad (\text{PTS1})$$

$$t_1 \text{ free but subject to } t_0 \leq t_1 \leq t_2 \text{ and } y(t_1) \text{ free} \quad (\text{PTS2})$$

The Hamiltonian function becomes a piecewise continuous, or piecewise differentiable function

$$H(t) = H(t, y(t), u(t), \lambda(t)) = \begin{cases} H_1(t) = F_1(t) + \lambda(t) G_1(t) & \text{if } t_0 \leq t < t_1 \\ H_2(t) = F_2(t) + \lambda(t) G_2(t) & \text{if } t_1 \leq t \leq t_2 \end{cases}$$

where the co-state variable is $\lambda : T \rightarrow \mathbb{R}$, and $H_i(t) = H_i(t, y(t), u(t), \lambda(t))$ for $i = 1, 2$.

Proposition 1. [*First order necessary conditions for the two-stage optimal control problem*] Let (y^*, u^*) be a solution to the OC problem PTS in which one of the conditions (PTS1), or (PTS2) is introduced. Then there is a piecewise continuous function $\lambda : T \rightarrow \mathbb{R}$, called co-state variable, such that (y^*, u^*, λ) satisfy the following conditions:

- the optimality condition:

$$\begin{aligned} H_{1,u}^*(t) &= 0, \text{ for } t \in [t_0, t_1^*) \\ H_{2,u}^*(t) &= 0, \text{ for } t \in [t_1^*, t_2] \end{aligned} \quad (10.2)$$

where $H_{i,u}^*(t) = H_{i,u}(t, y^*(t), u^*(t), \lambda(t))$ for $i = 1, 2$;

- the multiplier equation

$$\begin{aligned} \dot{\lambda} + H_{1,y}^*(t) &= 0, \text{ for } t \in [t_0, t_1^*) \\ \dot{\lambda} + H_{2,y}^*(t) &= 0, \text{ for } t \in [t_1^*, t_2] \end{aligned} \quad (10.3)$$

where $H_{i,y}^*(t) = H_{i,y}(t, y^*(t), u^*(t), \lambda(t))$ for $i = 1, 2$;

- the constraint of the problem:

$$\begin{aligned} \dot{y} &= G_1^*(t), \text{ for } t \in [t_0, t_1^*) \\ \dot{y} &= G_2^*(t), \text{ for } t \in [t_1^*, t_2] \end{aligned} \quad (10.4)$$

where $G_i^*(t) = G_i(t, y^*(t), u^*(t))$ for $i = 1, 2$;

- the adjoint condition associated to the initial values $(t_0, y(t_0))$: $y^*(t_0) = y_0$;
- the adjoint conditions associated to the terminal values $(t_2, y(t_2))$:

$$\lambda(t_2) (y^*(t_2) - y_2) = 0, \text{ and } \lambda(t_2) \geq 0; \quad (10.5)$$

- and the adjoint conditions associated to switching conditions (PTS1) and (PTS2) are
 - for problem (PTS1): assuming that $t_0 < t_1 < t_2$ the switching condition is

$$\lambda(t_1^-) = \lambda(t_1^+) \quad (10.6)$$

where $\lambda(t_1^-) = \lim_{t \uparrow t_1} \lambda(t)$ and $\lambda(t_1^+) = \lim_{t \downarrow t_1} \lambda(t)$ are the limits of the co-state variables determined from the first stage (i.e., from $t \in [t_0, t_1]$) and from the second stage (i.e., from $t \in [t_1, t_2]$) respectively;

- for problem (PTS2) there are two conditions,

$$\lambda(t_1^{*-}) = \lambda(t_1^{*+}) \quad (10.7)$$

where $\lambda(t_1^{*-}) = \lim_{t \uparrow t_1^*} \lambda(t)$ and $\lambda(t_1^{*+}) = \lim_{t \downarrow t_1^*} \lambda(t)$ together with one of the one of the following conditions allowing for the determination of the optimal switching time t_1^* :

$$\begin{aligned} t_1^* = t_0 < t_2 &\iff H_1^*(t_1^{*-}) < H_2^*(t_1^{*+}) \\ t_0 < t_1^* < t_2 &\iff H_1^*(t_1^{*-}) = H_2^*(t_1^{*+}) \\ t_0 < t_1^* = t_2 &\iff H_1^*(t_1^{*-}) > H_2^*(t_1^{*+}) \end{aligned} \quad (10.8)$$

where $H_1^*(t_1^{*-}) = \lim_{t \uparrow t_1^*} H_1(t)$ and $H_2^*(t_1^{*+}) = \lim_{t \downarrow t_1^*} H_2(t)$.

Proof. (Heuristic) Let u^* and y^* be the optimal control and state variable. The value functional, at the optimum, is, for (PTS2) problem,

$$J^* = \int_{t_0}^{t_1^*} F_1^*(t) dt + \int_{t_1^*}^{t_2} F_2^*(t) dt$$

and the associated Lagrangean is

$$L^* = J^* + \mu_0 (t_1^* - t_0) + \mu_2 (t_2 - t_1^*) + \psi (y^*(t_2) - y_2),$$

where the complementary slackness conditions should hold

$$\begin{aligned} \mu_0 (t_1^* - t_0) &= 0, \mu_0 \geq 0, \text{ and } t_1^* \geq t_0 \\ \mu_2 (t_2 - t_1^*) &= 0, \mu_2 \geq 0, \text{ and } t_1^* \leq t_2 \\ \psi (y^*(t_2) - y_2) &= 0, \psi \geq 0, \text{ and } y^*(t_2) \leq y_2. \end{aligned}$$

Introducing the admissible perturbations $y(t) = y^*(t) + \varepsilon \eta_y(t)$ to the state variable, $u(t) = u^*(t) + \varepsilon \eta_u(t)$ to the control variable and $t_1 = t_1^* + \varepsilon \tau_1$, yields the Gâteaux differential

$$\begin{aligned} \delta_{\eta(\cdot)} L[y^*, u^*; t_1^*] &= \int_{t_0}^{t_1^*} \left[H_{1,u}^*(t) \eta_u(t) + \left(H_{1,y}^*(t) + \dot{\lambda}(t) \right) \eta_y(t) \right] dt + \\ &+ \int_{t_1^*}^{t_2} \left[H_{2,u}^*(t) \eta_u(t) + \left(H_{2,y}^*(t) + \dot{\lambda}(t) \right) \eta_y(t) \right] dt \\ &+ \lambda(t_0) \eta(t_0) + (\lambda(t_1^{*+}) - \lambda(t_1^{*-})) \eta(t_1^*) + (\psi - \lambda(t_2) \eta(t_2)) \\ &+ \left(\mu_0 - \mu_2 + H_1^*(t_1^{*-}) - H_2^*(t_1^{*+}) \right) \tau_1. \end{aligned}$$

At the optimum $\delta_{\eta(\cdot)} L[y^*, u^*; t_1^*] = 0$ should be satisfied, together with the complementary slackness conditions for admissible perturbations. As the only constraint on the perturbation is $\eta(t_0) = 0$, at the optimum satisfies $H_{1,u}^*(t) = H_{1,y}^*(t) + \dot{\lambda}(t) = \dot{y} - G_1^*(t) = 0$ for every $t \in [t_0, t_1^{*-})$, $H_{2,u}^*(t) = H_{2,y}^*(t) + \dot{\lambda}(t) = \dot{y} - G_2^*(t) = 0$ for every $t \in (t_1^{*+}, t_2]$, $\lambda(t_2)(y^*(t_2) - y_2) = 0$, and $\lambda(t_1) = \lambda(t_1^*)$ if t_1 is fixed, or $\lambda(t_1^{*+}) = \lambda(t_1^{*-})$ together with $\mu_0 - \mu_2 + H_1^*(t_1^{*-}) - H_2^*(t_1^{*+}) = 0$ together with the associated complementary slackness conditions if t_1 should be optimally determined. \square

Switching costs: there are version of the problem in which there is a switching cost at time $t = t_1$, depending on the state of the problem, as $\Phi(t_1, y(t_1))$. In this case we have

- for the fixed switching time problem (??) instead of condition (10.6) we have

$$\lambda(t_1^-) + \Phi_y(t_1, y^*(t_1)) = \lambda(t_1^+)$$

$$\Phi_y(t, y) = \frac{\partial \Phi(t, y)}{\partial y}.$$

- for the free switching time problem (??) instead of condition (10.7) we have

$$\lambda(t_1^{*-}) + \Phi_y(t_1, y^*(t_1^*)) = \lambda(t_1^{*+})$$

and instead of conditions (10.8) we have

$$\begin{aligned} t_1^* = t_0 < t_2 &\iff H_1^*(t_1^{*-}) - \Phi_t(t_1, y^*(t_1^*)) < H_2^*(t_1^{*+}) \\ t_0 < t_1^* < t_2 &\iff H_1^*(t_1^{*-}) - \Phi_t(t_1, y^*(t_1^*)) = H_2^*(t_1^{*+}) \\ t_0 < t_1^* = t_2 &\iff H_1^*(t_1^{*-}) - \Phi_t(t_1, y^*(t_1^*)) > H_2^*(t_1^{*+}) \end{aligned}$$

$$\text{where } \Phi_t(t, y) = \frac{\partial \Phi(t, y)}{\partial t}.$$

Observations: we can extend this approach to multiple switching times.

References: Tomiyama (1985), Rossana (1989), Makris (2001). For an application to endogenous growth see Boucekine et al. (2004).

10.4 Constraints on state and control variables

Assume that the independent variable is time $t \in T = [0, T]$ and one of the following constraints exist: constraints on state variables such that $Q_2(y(t), t) \leq 0$, or constraints in the state and/or control variables such that $Q_1(y(t), u(t), t) \leq 0$, for every $t \in T$.

$$\begin{aligned} \max_{u(\cdot)} J[y, u] &= \int_0^T F(t, y(t), u(t)) dt \\ \text{subject to} \\ \dot{y} &= G(t, y(t), u(t)) \\ y(0) &= y_0 \text{ given} \\ Q_1(t, y(t), u(t)) &\geq 0, \text{ for any } t \in T \\ Q_2(t, y(t)) &\geq 0, \text{ for any } t \in T \\ R(y(T), T) &\geq 0. \end{aligned} \tag{10.9}$$

where $Q_1(\cdot) \geq 0$ is a joint constraint on the state variable and the control variable and $Q_2(\cdot) \geq 0$ is a pure state constraint.

In this problem we have potential points of discontinuity for the adjoint variable $\lambda(\cdot)$ when the constraints are

In this case an (informal) version of the Pontryagin maximum principle is presented in Hartl et al. (1995). Define the Hamiltonian function

$$H(y, u, \lambda_0, \lambda, t) = \lambda_0 F(y, u, t) + \lambda G(y, u, t),$$

and the Lagrangean

$$L(y, u, \lambda_0, \lambda, t) = H(y, u, \lambda_0, \lambda, t) + \nu_1 Q_1(y, u, t) + \nu_2 Q_2(y, t).$$

An informal version of the Pontryagin's principle states the following: If (y^*, u^*) is an optimum, then there is a scalar $\lambda_0 \in \mathbb{R}$, a piecewise function $\lambda : T \rightarrow \mathbb{R}$, Lagrange multipliers $\nu_1 : T \rightarrow \mathbb{R}$, and/or $\nu_2 : T \rightarrow \mathbb{R}$, variables $\zeta(t_i)$ at the times of discontinuity t_i for $\lambda(\cdot)$, and three constants α and β such that:

1. for every $t \in [0, T)$

$$\begin{aligned} L_u^*(t) &= 0 \\ \dot{\lambda} &= -L_y^*(t) \\ \dot{y} &= L_\lambda^*(t) = G(t, y^*(t), u^*(t)) \end{aligned}$$

$$\nu_1(t) \geq 0, \text{ and } \nu_1(t) Q_1^*(t) = 0$$

$$\nu_2(t) \geq 0, \text{ and } \nu_2(t) Q_2^*(t) = 0$$

2. at the terminal time $t = T$

$$\lambda(T^-) = \alpha Q_{2,y}^*(T) + \beta R_y^*(T)$$

$$\alpha \geq 0, \text{ and } \alpha Q_2^*(T) = 0$$

$$\beta \geq 0, \text{ and } \beta R^*(T) = 0.$$

3. for any time t_i at a boundary interval and for any contact time t_i , the co-state variable $\lambda(\cdot)$ may have a discontinuity given by

$$\lambda(t_i^-) = \lambda(t_i^+) + \eta(t_i) Q_{2,y}^*(t_i)$$

$$H^*(t_i^-) = H^*(t_i^+) + \eta(t_i) Q_{2,t}^*(t_i)$$

$$\eta(t_i) \geq 0, \text{ and } \eta(t_i) Q_2^*(t_i) = 0$$

where $\lambda(t_i^-) = \lim_{t \uparrow t_i} \lambda(t)$ and $\lambda(t_i^+) = \lim_{t \downarrow t_i} \lambda(t)$ and an analogous notation for $H^*(t)$.

References: Köhler (1980), Hartl et al. (1995).

10.5 Integral constraints

In this section we present an optimal control problem in which there is a integral constraint of the iso-perimetric type, that is a constraint involving the integration of a known function of the state,

and or control variables for all the domain of the independent variable. This case should not be confused to other types of optimal control problems in which there are integral constraints only for a sub-domain of the independent variable. While in the case we deal here, the constraint is of dimension zero (it is a scalar) in the second case the constraint is infinite-dimensional. This means that while in the case we address here we associate an adjoint variable, in the second case we to introduce an adjoint function.

Let the the independent variable be $x \in X \subseteq \mathbb{R}$, where $X = [x_0, x_1]$, the state variable be $y : X \rightarrow \mathbb{R}$, and the control variable be $u : X \rightarrow \mathbb{R}$.

We consider the following constraints

$$\int_{x_0}^{x_1} G_0(x, y(x), u(x)) dx \leq \bar{G} \quad (10.10a)$$

$$\frac{dy(x)}{dx} = G_1(x, y(x), u(x)) \quad x \in X \quad (10.10b)$$

$$x_0, x_1, y(x_0), y(x_1) \text{ free} \quad (10.10c)$$

where \bar{G} is a constant.

The problem is

$$\begin{aligned} & \max_{x_0, x_1, u(\cdot)} \int_{x_0}^{x_1} F(x, y(x), y'(x)) dx \\ & \text{subject to} \\ & \int_{x_0}^{x_1} G_0(x, y(x), u(x)) dx \leq \bar{G} \\ & \frac{dy(x)}{dx} = G_1(x, y(x), u(x)), \quad x \in X \\ & x_0, x_1, y(x_0), y(x_1) \text{ free} \end{aligned} \quad (\text{ICP})$$

This problem optimal control problem has one functional constraint of the iso-perimetric type, (10.10a), one ordinary differential equation constraint, (10.10b), and has free initial and terminal indices and free initial and terminal values for the state variable .

There are several versions for this problem. For instance: (1) the simplest problem is the one in which $x_0, x_1, y(x_0)$ and $y(x_1)$ are fixed; (2) the free terminal problem which is common in optimal control problems in which the index variable is time in which x_0 and $y(x_0)$ are known and x_1 and $y(x_1)$ are free; (3) a problem in which the limit values of the indices, x_0 and x_1 , are fixed and the state values, $y(x_0)$ and $y(x_1)$, are free; or (4) a problem in which the limit values of the indices, x_0 and x_1 , are free and the state values, $y(x_0)$ and $y(x_1)$, are fixed.

We define the Hamiltonian function

$$H(x, y, u, \lambda_0, \lambda_1) = F(x, y, u) - \lambda_0 G_0(x, y, u) + \lambda_1 G_1(x, y, u)$$

where λ_0 is a constant, and λ_1 is a mapping $\lambda_1 : X \rightarrow \mathbb{R}$. The maximized Hamiltonian, is

$$H^*(x) = H(x, y^*(x), y'^*(x), \lambda_0, \lambda_1(x)) = \max_{u(\cdot)} H(x, y(x), u(x), \lambda_0, \lambda_1(x)), \text{ for each } x \in X.$$

Proposition 2. *[First order necessary conditions for the integral-constrained optimal control problem] Let (y^*, u^*) be a solution to the OC problem (ICP). Then there is a variable λ_0 and a piecewise continuous function $\lambda : X \rightarrow \mathbb{R}$, such that $(y^*, u^*, \lambda_0, \lambda_1)$ satisfy the following conditions:*

- the optimality condition:

$$H_u^*(x) = 0, \text{ for } x \in [x_0^*, x_1^*] \quad (10.11)$$

- the multiplier equation

$$\lambda_1'(x) + H_y^*(x) = 0, \text{ for } x \in [x_0^*, x_1^*] \quad (10.12)$$

- initial and terminal conditions associated to the independent and state variables

$$\lambda_1(x_j^*) = 0, \text{ for } j = 0, 1 \quad (10.13a)$$

$$H^*(x_j^*) - \lambda_j(x_j^*) y^{*'}(x_j^*) = 0, \text{ for } j = 0, 1 \quad (10.13b)$$

- for admissible solutions, i.e., satisfying

$$\int_{x_0^*}^{x_1^*} G_0(x, y^*(x), u^*(x)) dx = \bar{G} \quad (10.14a)$$

$$y^{*'}(x) = G_1(x, y^*(x), u^*(x)) \text{ } x \in (x_0^*, x_1^*) \quad (10.14b)$$

Proof. The value functional at the optimum is

$$J^* = \int_{x_0^*}^{x_1^*} F(x, y^*(x), u^*(x)) dx. \quad (10.15)$$

Equivalently, substituting the definition of the Hamiltonian and using integration by parts

$$\begin{aligned} J^* &= \int_{x_0^*}^{x_1^*} \left(H(x, y^*(x), u^*(x), \lambda_0, \lambda_1(x)) - y^{*'}(x) \right) dx + \lambda_0 \bar{G} \\ &= \int_{x_0^*}^{x_1^*} \left(H(x, y^*(x), u^*(x), \lambda_0, \lambda_1(x)) + \lambda_1'(x) y^*(x) \right) dx + \lambda_1(x_1^*) y^*(x_1^*) - \lambda_1(x_0^*) y^*(x_0^*) + \lambda_0 \bar{G} \end{aligned}$$

Introduce the arbitrary (functional) perturbations $y^*(x) \rightarrow y(x) = y^*(x) + \varepsilon \eta_y(x)$, $u^*(x) \rightarrow u(x) = u^*(x) + \varepsilon \eta_u(x)$, and the (point) perturbations $x_t^* \rightarrow x_t = x_t^* + \varepsilon \chi_t$, for $t = 0, 1$ and $y_t^* \rightarrow y_t = y_t^* + \varepsilon \iota_t$, for $t = 0, 1$, such that

$$\iota(x_t^*) = \iota_t - y^{*'}(x_t^*) \chi_t, \text{ } t = 0, 1 \quad (10.16)$$

At the optimum $\delta J[y^*, u^*] = 0$ where the variational derivative is

$$\delta J[y^*, u^*] = \lim_{\varepsilon \rightarrow 0} \frac{\Delta J}{\varepsilon}$$

where $\Delta J = J[y^* + \varepsilon \iota, u^* + \varepsilon \eta_u] - J[y^*, u^*]$. Using derivations from the previous problems we find

$$\begin{aligned} \Delta J[y, u] = & \int_{x_0^*}^{x_1^*} \left[H(x, y^*(x) + \varepsilon \eta_y(x), u^*(x) + \varepsilon \eta_u(x), \lambda_0, \lambda_1(x)) - H(x, y^*(x), u^*(x), \lambda_0, \lambda_1(x)) + \right. \\ & \left. + \lambda_1'(x) (y^*(x) + \varepsilon \eta_y(x) - y^*(x)) \right] dx + \\ & + \lambda_1(x_1^*) (y^*(x_1^*) + \varepsilon \eta_y(x_1^*)) - \lambda_1(x_0^*) (y^*(x_0^*) + \varepsilon \eta_y(x_0^*)) - \lambda_1(x_1^*) y^*(x_1^*) + \lambda_1(x_0^*) y^*(x_0^*) + \\ & + \left(H(x, y^*(x), u^*(x), \lambda_0, \lambda_1(x))|_{x=x_1^*} \right) \chi_1 - \left(H(x, y^*(x), u^*(x), \lambda_0, \lambda_1(x))|_{x=x_0^*} \right) \chi_0 \end{aligned}$$

Using a first-order Taylor approximation and equation (10.16), collecting terms, factoring out and simplifying the notation we have,

$$\begin{aligned} \delta J[y, u] &= \int_{x_0^*}^{x_1^*} \left[H_u^*(x) \eta_u(x) + (H_y^*(x) + \lambda_1'(x)) \eta_y(x) \right] dx + \lambda_1(x_1^*) \eta_y(x_1^*) - \lambda_1(x_0^*) \eta_y(x_0^*) + \\ &+ H^*(x_1^*) \chi_1 - H^*(x_0^*) \chi_0 = \\ &= \int_{x_0^*}^{x_1^*} \left[H_u^*(x) \eta_u(x) + (H_y^*(x) + \lambda_1'(x)) \eta_y(x) \right] dx + \\ &+ \lambda_1(x_1^*) \iota_1 - \lambda_1(x_0^*) \iota_0 + (H^*(x_1^*) - \lambda_1(x_1^*) (y^*)'(x_1^*)) \chi_1 - (H^*(x_0^*) - \lambda_1(x_0^*) (y^*)'(x_0^*)) \chi_0, \end{aligned}$$

at the optimum $\delta J[y^*, u^*] = 0$ from which we derive equations (10.11)-(10.13b).
